

## FEATURES

- High performance 24-bit  $\Sigma$ - $\Delta$  ADC
- 115 dB dynamic range at 78.125 kHz output data rate
- 109 dB dynamic range at 312.5 kHz output data rate
- 312.5 kHz maximum fully filtered output word rate
- Pin-selectable oversampling rates of 64 $\times$ , 128 $\times$ , and 256 $\times$
- Low power mode
- Flexible serial peripheral interface (SPI)
- Fully differential modulator input
- On-chip differential amplifier for signal buffering
- On-chip reference buffer
- Full band, low-pass, finite impulse response (FIR) filter
- Overrange alert pin
- Digital gain correction registers
- Power-down mode
- Synchronization of multiple devices via the **SYNC** pin
- Daisy chaining

## APPLICATIONS

- Data acquisition systems
- Vibration analysis
- Instrumentation

## GENERAL DESCRIPTION

The **AD7764** is a high performance, 24-bit, sigma-delta ( $\Sigma$ - $\Delta$ ) analog-to-digital converter (ADC). It combines wide input bandwidth, high speed, and performance of 109 dB dynamic range at a 312.5 kHz output data rate. With excellent dc specifications, the converter is ideal for high speed data acquisition of ac signals where dc data is also required.

Using the **AD7764** eases front-end antialias filtering requirements, simplifying the design process significantly. The **AD7764** offers pin-selectable decimation rates of 64 $\times$ , 128 $\times$ , and 256 $\times$ . Other features include an integrated buffer to drive the reference, as well as a fully differential amplifier to buffer and level shift the input to the modulator.

An overrange alert pin indicates when an input signal exceeds the acceptable range. The addition of internal gain and internal overrange registers makes the **AD7764** a compact, highly integrated data acquisition device requiring minimal peripheral components.

The **AD7764** also offers a low power mode, significantly reducing power dissipation without reducing the output data rate or available input bandwidth.

## FUNCTIONAL BLOCK DIAGRAM

Figure 1.

Table 1. Related Devices

Device No.	Description
<a href="#">AD7760</a>	2.5 MSPS, 100 dB, parallel output, on-chip buffer
<a href="#">AD7762</a>	625 kSPS, 109 dB, parallel output, on-chip buffer
<a href="#">AD7763</a>	625 kSPS, 109 dB, serial output, on-chip buffers
<a href="#">AD7765</a>	156 kSPS, 112 dB, serial output, on-chip buffers
<a href="#">AD7766</a>	128 kSPS/64 kSPS/32 kSPS, 8.5 mW, 109 dB SNR
<a href="#">AD7767</a>	128 kSPS/64 kSPS/32 kSPS, 8.5 mW, 109 dB SNR

The differential input is sampled at up to 40 MSPS by an analog modulator. The modulator output is processed by a series of low-pass filters. The external clock frequency applied to the **AD7764** determines the sample rate, filter corner frequencies, and output word rate.

The **AD7764** device boasts a full band, on-board FIR filter. The full stop-band attenuation of the filter is achieved at the Nyquist frequency. This feature offers increased protection from signals that lie above the Nyquist frequency being aliased back into the input signal bandwidth.

The reference voltage supplied to the **AD7764** determines the input range. With a 4 V reference, the analog input range is  $\pm 3.2768$  V differential, biased around a common mode of 2.048 V. This common-mode biasing is achieved using the on-chip differential amplifier, further reducing the external signal conditioning requirements.

The **AD7764** is available in a 28-lead TSSOP package and is specified over the industrial temperature range of  $-40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$ .

<sup>1</sup> See the Terminology section.

<sup>2</sup> SNR specifications in decibels are referred to a full-scale input, FS, and are tested with an input signal at 0.5 dB below full scale, unless otherwise specified.

<sup>3</sup> The output data rate (ODR) = [(MCLK/2)]/decimation rate. That is, the maximum ODR for the AD7764 = [(40 MHz)/2]/64 = 312.5 kHz.

<sup>4</sup> Tested with a 400 μA load current.

<sup>5</sup> Specified min and max values relate to the common mode voltage at which the protection circuitry on the pins (V<sub>IN</sub>A+ and V<sub>IN</sub>A-) starts to turn on. Prior to this turn on, the THD of the AD7764 degrades at common modes approaching 2 V, or on the lower side approaching 1 V.

<sup>6</sup> Tested at MCLK = 40 MHz. This current scales linearly with the applied MCLK frequency.

<sup>7</sup> Tested at 125°C.

## TIMING SPECIFICATIONS

$AV_{DD1} = DV_{DD} = 2.5\text{ V}$ ,  $AV_{DD2} = AV_{DD3} = AV_{DD4} = 5\text{ V}$ ,  $V_{REF+} = 4.096\text{ V}$ ,  $T_A = 25^\circ\text{C}$ ,  $C_{LOAD} = 25\text{ pF}$ .

Table 3.

Parameter	Limit at $T_{MIN}$ , $T_{MAX}$			Unit	Description
	Min	Typ	Max		
$f_{MCLK}$	500		40	kHz	Applied master clock frequency
$f_{ICLK}$	250		20	MHz	Internal modulator clock derived from MCLK
$t_1$		$1 \times t_{ICLK}$		sec	SCO high period
$t_2$		$1 \times t_{ICLK}$		sec	SCO low period
$t_3$		1	2.5	ns	SCO rising edge to $\overline{FSO}$ falling edge
$t_4$		2	3.5	ns	Data access time, $\overline{FSO}$ falling edge to data active
$t_5$			8	ns	MSB data access time, SDO active to SDO valid
$t_6$	40			ns	Data hold time (SDO valid to SCO rising edge)
$t_7$			9.5	ns	Data access time (SCO rising edge to SDO valid)
$t_8$		2	2.5	ns	SCO rising edge to $\overline{FSO}$ rising edge
$t_9$			$32 \times t_{SCO}$	sec	$\overline{FSO}$ low period
$t_{10}$	12			ns	Setup time from $\overline{FSI}$ falling edge to SCO falling edge
$t_{11}$	$1 \times t_{SCO}$			sec	$\overline{FSI}$ low period
$t_{12}^1$			$32 \times t_{SCO}$	sec	$\overline{FSI}$ low period
$t_{13}$	12			ns	SDI setup time for the first data bit
$t_{14}$	12			ns	SDI setup time
$t_{15}$			0	ns	SDI hold time
$t_{R\ MIN}$	$1 \times t_{MCLK}$			sec	Minimum time for a valid $\overline{RESET}$ pulse
$t_{R\ HOLD}$	5			ns	Minimum time between the MCLK rising edge and $\overline{RESET}$ rising edge
$t_{R\ SETUP}$	5			ns	Minimum time between the $\overline{RESET}$ rising edge and MCLK rising edge
$t_{S\ MIN}$	$4 \times t_{MCLK}$			sec	Minimum time for a valid $\overline{SYNC}$ pulse
$t_{S\ HOLD}$	5			ns	Minimum time between the MCLK falling edge and $\overline{SYNC}$ rising edge
$t_{S\ SETUP}$	5			ns	Minimum time between the $\overline{SYNC}$ rising edge and MCLK falling edge

<sup>1</sup> This is the maximum time  $\overline{FSI}$  can be held low when writing to an individual device (a device that is not daisy-chained).

## ABSOLUTE MAXIMUM RATINGS

$T_A = 25^\circ\text{C}$ , unless otherwise noted.

Table 4.

Parameter	Rating
$AV_{DD1}$ to Ground	-0.3 V to +2.8 V
$AV_{DD2}$ , $AV_{DD3}$ , $AV_{DD4}$ to Ground	-0.3 V to +6 V
$DV_{DD}$ to Ground	-0.3 V to +2.8 V
$V_{INA+}$ , $V_{INA-}$ to Ground <sup>1</sup>	-0.3 V to +6 V
$V_{IN+}$ , $V_{IN-}$ to Ground <sup>1</sup>	-0.3 V to +6 V
Digital Input Voltage to Ground <sup>2</sup>	-0.3 V to +2.8 V
$V_{REF+}$ to Ground <sup>3</sup>	-0.3 V to +6 V
AGND to DGND	-0.3 V to +0.3 V
Input Current to Any Pin Except Supplies <sup>4</sup>	$\pm 10$ mA
Operating Temperature Range, Commercial	$-40^\circ\text{C}$ to $+85^\circ\text{C}$
Storage Temperature Range	$-65^\circ\text{C}$ to $+150^\circ\text{C}$
Junction Temperature	$150^\circ\text{C}$
$\theta_{JA}$ Thermal Impedance (1s0p) <sup>5</sup>	$143^\circ\text{C}/\text{W}$
$\theta_{JA}$ Thermal Impedance (2s2p) <sup>6,7</sup>	$71.1^\circ\text{C}/\text{W}$
$\theta_{JC}$ Thermal Impedance <sup>8</sup>	$20^\circ\text{C}/\text{W}$
Solder Reflow Temperature <sup>9</sup>	$260^\circ\text{C}$
ESD	1 kV

<sup>1</sup> The absolute maximum voltage for  $V_{IN-}$ ,  $V_{IN+}$ ,  $V_{INA-}$ , and  $V_{INA+}$  is 6.0 V or  $AV_{DD3} + 0.3$  V, whichever is lower.

<sup>2</sup> The absolute maximum voltage on the digital input is 3.0 V or  $DV_{DD} + 0.3$  V, whichever is lower.

<sup>3</sup> The absolute maximum voltage on the  $V_{REF+}$  input is 6.0 V or  $AV_{DD4} + 0.3$  V, whichever is lower.

<sup>4</sup> Transient currents of up to 100 mA do not cause SCR latch-up.

<sup>5</sup> 1s0p means a single-layer printed circuit board (PCB), which includes one signal layer and zero power layers.

<sup>6</sup> 2s2p means a 4-layer PCB, which includes 2 signal layers and 2 power layers.

<sup>7</sup>  $\theta_{JA}$  for a 2s2p PCB is derived from simulation.

<sup>8</sup> The revised  $\theta_{JC}$  (thermal impedance) is derived from simulation.

<sup>9</sup> Maximum reflow temperature as per JEDEC J-SDT-020.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

### ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 5. Pin Configuration

Table 5. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	V <sub>INA-</sub>	Negative Input to the Differential Amplifier.
2	V <sub>OUTA+</sub>	Positive Output from the Differential Amplifier.
3	V <sub>INA+</sub>	Positive Input to the Differential Amplifier.
4	V <sub>OUTA-</sub>	Negative Output from the Differential Amplifier.
5	V <sub>IN-</sub>	Negative Input to the Modulator.
6	V <sub>IN+</sub>	Positive Input to the Modulator.
7, 21	AV <sub>DD2</sub>	5 V Power Supply. Decouple Pin 7 to AGND3 (Pin 8) with a 100 nF capacitor. Decouple Pin 21 to AGND1 (Pin 23) with a 100 nF capacitor.
8	AGND3	Power Supply Ground for the Analog Circuitry.
9	OVERRANGE	Overrange Pin. This pin outputs a logic high to indicate that the user applied an analog input that is approaching the limit of the analog input to the modulator.
10	SCO	Serial Clock Out. This clock signal is derived from the internal ICLK signal. The frequency of this clock is equal to ICLK. See the Clocking the AD7764 section for more information.
11	$\overline{\text{FSO}}$	Frame Sync Out. This signal frames the serial data output and is 32 SCO periods wide.
12	SDO	Serial Data Out. Data and status are output on this pin during each serial transfer. Each bit is clocked out on an SCO rising edge and is valid on the falling edge. See the AD7764 Serial Interface section for further details.
13	SDI	Serial Data In. The first data bit (MSB) must be valid on the next SCO falling edge after the $\overline{\text{FSI}}$ event is latched. Thirty-two bits are required for each write; the first 16-bit word contains the device and register address, and the second word contains the data. See the AD7764 Serial Interface section for more information.
14	$\overline{\text{FSI}}$	Frame Sync Input. The status of this pin is checked on the falling edge of SCO. If this pin is low, then the first data bit is latched in on the next SCO falling edge. See the AD7764 Serial Interface section for more information.
15	$\overline{\text{SYNC}}$	Synchronization Input. A falling edge on this pin resets the internal filter. Use this pin to synchronize multiple devices in a system. See the Synchronization section for more information.
16	$\overline{\text{RESET/PWRDWN}}$	Reset/Power-Down Pin. When a logic low is sensed on this pin, the device is powered down and all internal circuitry is reset.
17	DV <sub>DD</sub>	2.5 V Power Supply for the Digital Circuitry and FIR Filter. Decouple this pin to the ground plane with a 100 nF capacitor.
18	DEC_RATE	Decimation Rate Pin. This pin selects one of the three decimation rate modes. When 2.5 V is applied to this pin, a decimation rate of 64× is selected. Select a decimation rate of 128× by leaving this pin floating. Select a decimation rate of 256× by setting this pin to ground.
19	MCLK	Master Clock Input. A low jitter digital clock must be applied to this pin. The output data rate depends on the frequency of this clock. See the Clocking the AD7764 section for more information.
20	AGND2	Power Supply Ground for the Analog Circuitry.
22	R <sub>BIAS</sub>	Bias Current Setting Pin. This pin must be decoupled to the ground plane. For more information, see the Bias Resistor Selection section.

Pin No.	Mnemonic	Description
23	AGND1	Power Supply Ground for the Analog Circuitry.
24	AV <sub>DD1</sub>	2.5 V Power Supply for the Modulator. Decouple this pin to AGND1 (Pin 23) with a 100 nF capacitor.
25	AV <sub>DD4</sub>	3.3 V to 5 V Power Supply for the Reference Buffer. Decouple this pin to AGND1 (Pin 23) with a 100 nF capacitor.
26	REFGND	Reference Ground. This pin is the ground connection for the reference voltage.
27	V <sub>REF+</sub>	Reference Input.
28	AV <sub>DD3</sub>	3.3 V to 5 V Power Supply for the Differential Amplifier. Decouple this pin to the ground plane with a 100 nF capacitor.

## TYPICAL PERFORMANCE CHARACTERISTICS

$AV_{DD1} = DV_{DD} = 2.5\text{ V}$ ,  $AV_{DD2} = AV_{DD3} = AV_{DD4} = 5\text{ V}$ ,  $V_{REF+} = 4.096\text{ V}$ , MCLK amplitude = 5 V,  $T_A = 25^\circ\text{C}$ . Linearity plots measured to 16-bit accuracy. Input signal reduced to avoid modulator overload and digital clipping; fast Fourier transforms (FFTs) of  $-0.5\text{ dB}$  tones are generated from 262,144 samples in normal power mode. All other FFTs are generated from 8192 samples.

## TERMINOLOGY

### Signal-to-Noise Ratio (SNR)

SNR is the ratio of the rms value of the actual input signal to the rms sum of all other spectral components below the Nyquist frequency, excluding harmonics and dc. The value for SNR is expressed in decibels (dB).

### Total Harmonic Distortion (THD)

THD is the ratio of the rms sum of the harmonics to the fundamental. For the AD7764, THD is defined as

$$THD(\text{dB}) = 20 \log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1}$$

where:

$V_2$ ,  $V_3$ ,  $V_4$ ,  $V_5$ , and  $V_6$  are the rms amplitudes of the second to the sixth harmonics.

$V_1$  is the rms amplitude of the fundamental.

### Nonharmonic Spurious-Free Dynamic Range (SFDR)

Nonharmonic SFDR is the ratio of the rms signal amplitude to the rms value of the peak spurious spectral component, excluding harmonics.

### Dynamic Range

Dynamic range is the ratio of the rms value of the full scale to the rms noise measured with the inputs shorted together. The value for dynamic range is expressed in decibels.

### Intermodulation Distortion

With inputs consisting of sine waves at two frequencies,  $f_a$  and  $f_b$ , any active device with nonlinearities creates distortion products at sum and difference frequencies of  $m f_a \pm n f_b$ , where  $m, n = 0, 1, 2, 3$ , and so on. Intermodulation distortion terms are those for which neither  $m$  nor  $n$  is equal to 0. For example, the second-order terms include  $(f_a + f_b)$  and  $(f_a - f_b)$ , while the third-order terms include  $(2f_a + f_b)$ ,  $(2f_a - f_b)$ ,  $(f_a + 2f_b)$ , and  $(f_a - 2f_b)$ .

The AD7764 is tested using the CCIF standard, where two input frequencies near the top end of the input bandwidth are used.

In this case, the second-order terms are typically distanced in frequency from the original sine waves, and the third-order terms are typically at a frequency close to the input frequencies. As a result, the second- and third-order terms are specified separately. The calculation of the intermodulation distortion is per the THD specification, where the calculation is the ratio of the rms sum of the individual distortion products to the rms amplitude of the sum of the fundamentals, expressed in decibels.

### Integral Nonlinearity (INL)

INL is the maximum deviation from a straight line passing through the endpoints of the ADC transfer function.

### Differential Nonlinearity (DNL)

DNL is the difference between the measured and the ideal 1 LSB change between any two adjacent codes in the ADC.

### Zero Error

Zero error is the difference between the ideal midscale input voltage (when both inputs are shorted together) and the actual voltage producing the midscale output code.

### Zero Error Drift

Zero error drift is the change in the actual zero error value due to a temperature change of 1°C. It is expressed as a percentage of full scale at room temperature.

### Gain Error

The first code transition (from 100 ... 000 to 100 ... 001) occurs for an analog voltage 1/2 LSB above the nominal negative full scale. The last code transition (from 011 ... 110 to 011 ... 111) occurs for an analog voltage 1 1/2 LSB below the nominal full scale. The gain error is the deviation of the difference between the actual level of the last transition and the actual level of the first transition, from the difference between the ideal levels.

### Gain Error Drift

Gain error drift is the change in the actual gain error value due to a temperature change of 1°C. It is expressed as a percentage of full scale at room temperature.

## THEORY OF OPERATION

The AD7764 features an on-chip fully differential amplifier to feed the  $\Sigma$ - $\Delta$  modulator pins, an on-chip reference buffer, and a FIR filter block to perform the required digital filtering of the  $\Sigma$ - $\Delta$  modulator output. Using this  $\Sigma$ - $\Delta$  conversion technique with the added digital filtering, the analog input is converted to an equivalent digital word.

### $\Sigma$ - $\Delta$ MODULATION AND DIGITAL FILTERING

The input waveform applied to the modulator is sampled, and an equivalent digital word is output to the digital filter at a rate equal to  $f_{CLK}$ . By employing oversampling, the quantization noise is spread across a wide bandwidth from 0 to  $f_{CLK}$ . This means that the noise energy contained in the signal band of interest is reduced (see Figure 30). To further reduce the quantization noise, a high-order modulator is employed to shape the noise spectrum so that most of the noise energy is shifted out of the signal band (see Figure 31).

Figure 30.  $\Sigma$ - $\Delta$  ADC, Quantization Noise

Figure 31.  $\Sigma$ - $\Delta$  ADC, Noise Shaping

Figure 32.  $\Sigma$ - $\Delta$  ADC, Digital Filter Cutoff Frequency

The modulator sampling rate,  $f_{CLK}$ , is dependent on the power mode chosen. Table 6 details the relationship between MCLK and  $f_{CLK}$  across power mode. The AD7764 low power mode divides the MCLK by a factor of 4, reducing current consumption in both the analog and digital domains.

Table 6. Modulator Sampling Rate vs. Power Mode

Power Mode	Modulator Sampling Rate ( $f_{CLK}$ )
Normal	MCLK/2
Low	MCLK/4

The digital filtering that follows the modulator removes the large out-of-band quantization noise (see Figure 32) while also reducing the data rate from  $f_{CLK}$  at the input of the filter to  $f_{CLK}/64$  or less at the output of the filter, depending on the decimation rate used.

Figure 33. Filter Frequency Response (312.5 kHz ODR)

The AD7764 employs a sequence of three FIR filters in series to provide a digital filter with a low ripple pass band, a steep transition band, and excellent stop-band rejection, which starts at the Nyquist frequency. Achieving the stop-band rejection at the Nyquist frequency is beneficial because it prevents signals slightly greater than the Nyquist frequency, which are not protected by an external antialias filter from aliasing back in-band.

The AD7764 digital filter allows data to be output at three different output data rates (for any given MCLK input frequency) through setting the decimation ratio through the series of filters.

The first filter receives data from the modulator at  $f_{CLK}$  MHz, where it is decimated 4 $\times$  to the output data at ( $f_{CLK}/4$ ) MHz. The second filter allows the decimation rate to be chosen from 8 $\times$  to 32 $\times$ . The third filter has a fixed decimation rate of 2 $\times$ .

Digital filters exhibit a group delay and settling time. The group delay of the filter is the delay from the change in analog input to when it is output by the digital filter. It is comprised of the computation plus the filter delays. The delay until valid data is available (when the FILTER\_SETTLE status bit is set) is approximately twice the filter delay plus the computation delay.

The group delay and settling time of a digital filter is apparent in the behavior of the ADC response to a SYNC input pulse.

Table 8 and Table 9 describe the response of the AD7764 in both normal and low power modes to a SYNC pulse, in addition to providing the group delay and settling times. Figure 34 shows the effect of SYNC and the subsequent signals from the AD7764.

The SYNC rising edge sets a known point in time from which the digital filter begins to process inputs from the modulator. This is useful in building a simultaneous sampling solution with multiple AD7764 devices, all clocked by the same MCLK.

The logic level of the SYNC pin is sampled by the rising edge of MCLK. Transitioning SYNC from low to high on an MCLK falling edge is recommended. Following the rising edge of SYNC, a number of MCLK periods pass before the first falling edge of FSO indicates a conversion output; this number of MCLK periods is defined as t<sub>SYNC\_OFFSET</sub>. Beyond t<sub>SYNC\_OFFSET</sub>, a number of conversion periods, each indicated by the falling edge of FSO, occur before the data from the filter is fully settled. During this time, outputs from the ADC have data that is a filtered mix of inputs to the modulator both before and after the time at which the SYNC signal transitioned from logic low to logic high.

All outputs from the ADC exhibit a group delay. The constant delay, due to the digital filter, is described by the number of conversion periods (t<sub>ODR</sub>) that pass between a change occurring on the analog input being seen on the digital conversion output. Figure 34 illustrates the group delay, showing a scenario where there is a step change on the analog inputs after the filter initially settles. As shown, a given number of periods of the output data rate occur before the digital output shows the step change.

Table 7. Group Delay (t<sub>GD\_ODR</sub>) Expressed in Periods of the Output Data Rate

Decimation Rate	Group Delay (t <sub>GD_ODR</sub> ) in Output Data Rate Periods	
	Normal Power Mode	Low Power Mode
64x	28	29
128x	28	28
256x	28	28

Because the group delay is not an exact number of conversion periods, a more precise way to describe the term is in MCLK periods. The exact region within a given conversion period where the analog input change occurs determines which output data period the ADC output responds to with a change in the digital output. Figure 34 shows that, if the step change on the input occurs at later point in time within the output period, the digital output remains updated within the same ODR period.

Described as the fine group delay, t<sub>GD\_MCLK</sub>, this delay consists of computation delay added to the actual delay through the filter provided in MCLK periods. Expressing the group delay in this manner allows it to be shown independent of the discrete steps of the ADC output data rate.

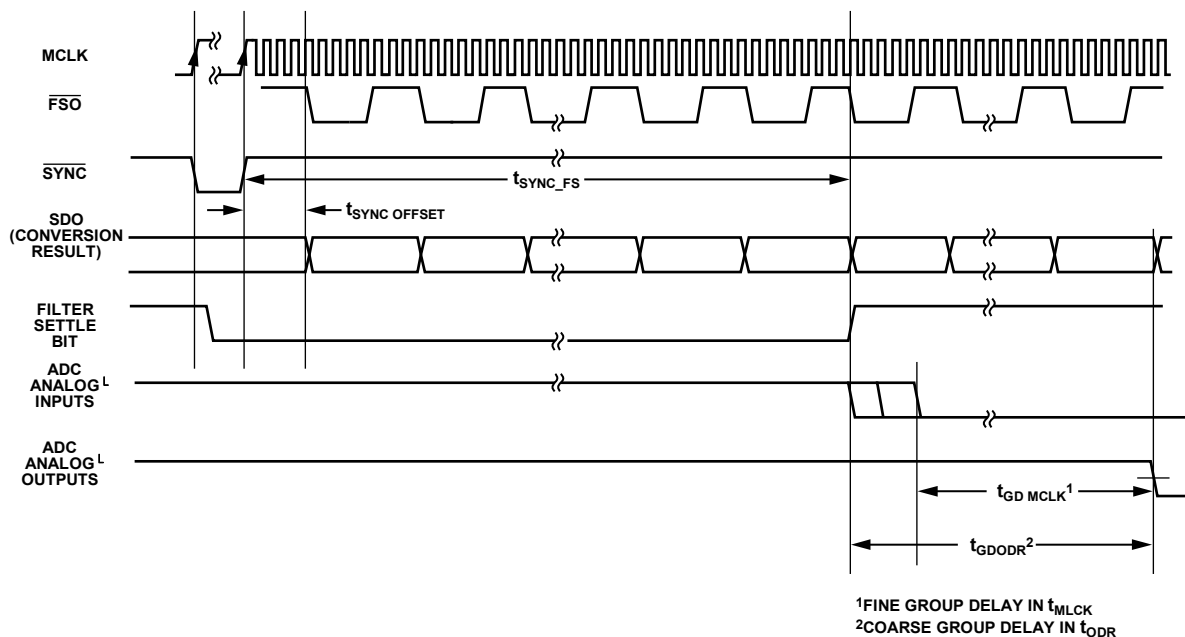

Figure 34. AD7764 Digital Filtering; Response to SYNC, Settling Time, and Group Delay

Table 8. Filter Group Delay and Settling Time in Normal Power Mode

Decimation Rate	Filter Computation Delay ( $t_{MCLK}$ )	Filter Delay ( $t_{MCLK}$ )	$t_{GDMCLK}$ ADC Group Delay ( $t_{MCLK}$ )	$t_{SYNC\_OFFSET}$ ( $t_{MCLK}$ )	$t_{SYNC\_FS}$ SYNC to FILTER SETTLE Bit ( $t_{MCLK}$ )	Modulator Sampling Rate ( $f_{ICLK}$ )	Oversampling Ratio (OSR)	Filter Pass Band	Output Data Rate (ODR)

### AD7764 ANTIALIAS PROTECTION

The decimation of the AD7764, along with its counterparts in the AD776x family, namely the AD7760, AD7762, AD7763, and AD7765, provides top of the range antialias protection.

The decimation filter of the AD7764 features more than 115 dB of attenuation across the full stop band, which ranges from the Nyquist frequency, namely  $ODR/2$ , up to  $I_{CLK} - ODR/2$  (where  $ODR$  is the output data rate). Starting the stop band at the Nyquist frequency prevents any signal component above Nyquist (and up to  $I_{CLK} - ODR/2$ ) from aliasing into the desired signal bandwidth.

Figure 33 shows the frequency response of the decimation filter when the AD7764 is operated with a 40 MHz MCLK in decimate  $\times 128$  mode. Note that the first stop-band frequency occurs at Nyquist. The frequency response of the filter scales with both the decimation rate chosen and the MCLK frequency applied. When using low power mode, the modulator sample rate is  $MCLK/4$ .

Taking as an example the AD7764 in normal power and in decimate  $\times 128$  mode, the first possible alias frequency is at the  $I_{CLK}$  frequency minus the pass band of the digital filter (see Figure 35).

Figure 35. Antialias Example Using the AD7764 in Normal Mode, Decimate  $\times 128$  Using  $MCLK/2 = I_{CLK} = 20$  MHz

06518-213

### INPUT STRUCTURE

The AD7764 requires a 4.096 V input to the reference pin,  $V_{REF+}$ , supplied by a high precision reference, such as the ADR444. Because the input to the  $\Sigma$ - $\Delta$  modulator of the device is fully differential, the effective differential reference range is 8.192 V.

$$V_{REF+} + (Diff) = 2 \times 4.096 = 8.192 \text{ V}$$

As is inherent in  $\Sigma$ - $\Delta$  modulators, only a certain portion of this full reference can be used. With the AD7764, 80% of the full differential reference can be applied to the differential inputs of the modulator.

$$Modulator\_Input_{FULL\_SCALE} = 8.192 \text{ V} \times 0.8 = 6.5536 \text{ V}$$

This means that a maximum of  $\pm 3.2768 \text{ V}$  p-p full scale can be applied to each of the AD7764 modulator inputs (Pin 5 and Pin 6), with the AD7764 being specified with an input  $-0.5 \text{ dBFS}$  from full scale ( $-0.5 \text{ dBFS}$ ). The AD7764 modulator inputs must have a common-mode input of 2.048 V.

Figure 36 shows the relative scaling between the differential voltages applied to the modulator pins and the respective 24-bit, twos complement digital outputs.

Figure 36. AD7764 Scaling: Modulator Input Voltage vs. Digital Output Code

065154-120

**ON-CHIP DIFFERENTIAL AMPLIFIER**

The AD7764 contains an on-board differential amplifier recommended to drive the modulator input pins. Pin 1, Pin 2, Pin 3, and Pin 4 on the AD7764 are the differential input and output pins of the amplifier. The external components,  $R_{IN}$ ,  $R_{FB}$ ,  $C_{FB}$ ,  $C_S$ , and  $R_M$ , are placed around Pin 1 through Pin 6 to create the recommended configuration.

To achieve the specified performance, configure the differential amplifier as a first-order antialias filter, as shown in Figure 37, using the component values listed in Table 10. The inputs to the differential amplifier are then routed through the external component network before being applied to the modulator inputs,  $V_{IN-}$  and  $V_{IN+}$  (Pin 5 and Pin 6). Using the optimal values in the table as an example yields a 25 dB attenuation at the first alias point of 19.6 MHz.

Figure 37. Differential Amplifier Configuration

**Table 10. On-Chip Differential Filter Component Values**

Value	$R_{IN}$ (k $\Omega$ )	$R_{FB}$ (k $\Omega$ )	$R_M$ ( $\Omega$ )	$C_S$ (pF)	$C_{FB}$ (pF)	$C_M$ (pF)
Optimal	4.75	3.01	43	8.2	47	33
Tolerance Range <sup>1</sup>	2.37 to 5.76	2.4 to 4.87	36 to 47	0 to 10	20 to 100	33 to 56

<sup>1</sup> The values shown are the acceptable tolerances for each component when altered relative to the optimal values that achieve the stated specifications of the device.

The range of values for each of the components in the differential amplifier configuration is listed in Table 10. When using the differential amplifier to gain the input voltages to the required modulator input range, it is recommended to implement the gain function by changing  $R_{IN}$  and leaving  $R_{FB}$  as the listed optimal value.

The common-mode input at each of the differential amplifier input pins ( $V_{IN+}$  and  $V_{IN-}$ ) can range from 0.8 V dc to 2.2 V dc. The amplifier has a constant output common-mode voltage of 2.048 V, that is,  $V_{REF}/2$ , the requisite common mode voltage for the modulator input pins ( $V_{IN+}$  and  $V_{IN-}$ ).

Figure 38 shows the signal conditioning that occurs using the differential amplifier configuration shown in Table 10 with a  $\pm 2.5$  V input signal to the differential amplifier. The amplifier in this example is biased around ground and is scaled to provide  $\pm 3.0935$  V p-p ( $-0.5$  dBFS) on each modulator input with a 2.048 V common mode.

Figure 38. Differential Amplifier Signal Conditioning

To obtain maximum performance from the AD7764, it is recommended to drive the ADC with differential signals. Figure 39 shows how a bipolar, single-ended signal biased around ground drives the AD7764 with the use of an external operational amplifier, such as the AD8021.

Figure 39. Single-Ended to Differential Conversion

### MODULATOR INPUT STRUCTURE

The AD7764 employs a double sampling front end, as shown in Figure 40. For simplicity, only the equivalent input circuitry for  $V_{IN+}$  is shown. The equivalent circuitry for  $V_{IN-}$  is the same.

Figure 40. Equivalent Input Circuit

The SS1 and SS3 sampling switches are driven by ICLK, whereas the SS2 and SS4 sampling switches are driven by  $\overline{I}CLK$ . When ICLK is high, the analog input voltage is connected to CS1. On the falling edge of ICLK, the SS1 and SS3 switches open, and the analog input is sampled on CS1. Similarly, when ICLK is low, the analog input voltage is connected to CS2. On the rising edge of ICLK, the SS2 and SS4 switches open, and the analog input is sampled on CS2.

The CPA, CPB1, and CPB2 capacitors represent parasitic capacitances that include the junction capacitances associated with the MOS switches.

Table 11. Equivalent Component Values

CS1 (pF)	CS2 (pF)	CPA (pF)	CPB1/CPB2 (pF)
13	13	13	5

### DRIVING THE MODULATOR INPUTS DIRECTLY

The AD7764 can be configured so that the on-board differential amplifier can be disabled and the modulator can be driven directly using discrete amplifiers. This allows the user to lower the power dissipation.

To power down the on board differential amplifier, the user issues a write to set the AMP OFF bit in the control register to logic high (see Figure 41).

Figure 41. Writing to the AD7764 Control Register, Turning Off the On-Board Differential Amplifier

The AD7764 modulator inputs must have a common-mode voltage of 2.048 V and adhere to the amplitudes as described in the Input Structure section.

An example of a typical circuit to drive the AD7764 for applications requiring excellent ac and dc performance is shown in Figure 42. Either the AD8606 or AD8656 can drive the AD7764 modulator inputs directly.

Best practice is to short the differential amplifier inputs to ground through the typical input resistors and leave the typical feedback resistors in place.

1 –0.5dBFS INPUT SIGNAL AS DESCRIBED IN INPUT STRUCTURE SECTION.  
2 SET C1 AND C2 AS REQUIRED FOR APPLICATION INPUT BW AND ANTI-ALIAS REQUIREMENT.

Figure 42. Driving the AD7764 Modulator Inputs Directly from a Single-Ended Source (On-Board Differential Amplifier Powered Down)

## AD7764 SERIAL INTERFACE

### READING DATA

The AD7764 uses fully synchronous serial data interface where the ADC is the master providing frame, serial clock, and serial data outputs. The timing diagram in Figure 2 shows how the AD7764 transmits conversion results.

The data read from the AD7764 is clocked out using the serial clock output (SCO). The SCO frequency is half that of the MCLK input to the AD7764.

The conversion result output on the serial data output (SDO) line is framed by the frame synchronization output, FSO, which is sent logic low for 32 SCO cycles. Each bit of the new conversion result is clocked onto the SDO line on the rising SCO edge and is valid on the falling SCO edge. The 32-bit result consists of the 24 data bits followed by five status bits followed further by three zeros. The five status bits are listed in Table 12 and described in this section.

**Table 12. Status Bits During a Data Read**

D7	D6	D5	D4	D3
FILTER_SETTLE	OVR	LPWR	DEC_RATE 1	DEC_RATE 0

The FILTER\_SETTLE bit indicates whether the data output from the AD7764 is valid. After resetting the device (using the RESET pin) or clearing the digital filter (using the SYNC pin), the FILTER\_SETTLE bit goes logic low to indicate that the full settling time of the filter has not yet passed and that the data is not yet valid. The FILTER\_SETTLE bit also goes to zero when the input to the device asserts the overrange alerts.

The OVR (overrange) bit is described in the Overrange Alerts section.

The LPWR bit is set to logic high when the AD7764 operates in low power mode. See the Power Modes section for further details.

The DEC\_RATE 1 bit and the DEC\_RATE 0 bit indicate the decimation ratio used. Table 13 is a truth table for the decimation rate bits.

**Table 13. Decimation Rate Status Bits**

Decimate	DEC_RATE 1	DEC_RATE 0
64×	0	1
128×	1	X <sup>1</sup>
256×	0	0

<sup>1</sup> X means don't care. If the DEC\_RATE 1 bit is set to 1, the AD7764 is in decimate 128× mode.

### READING STATUS AND OTHER REGISTERS

The AD7764 features a gain correction register, an overrange register, and a read only status register. To read back the contents of these registers, the user must first write to the control register of the device and set the bit that corresponds to the register to be read. The next read operation outputs the contents of the selected register (on the SDO pin) instead of a conversion result.

To ensure that the next read cycle contains the contents of the register written to, the write operation to that register must be completed a minimum of  $8 \times t_{SCO}$  before the falling edge of FSO, which indicates the start of the next read cycle. See Figure 4 for further details.

The AD7764 Registers section provides more information on the relevant bits in the control register.

### WRITING TO THE AD7764

A write operation to the AD7764 is shown in Figure 3. The serial writing operation is synchronous to the SCO signal. The status of the frame synchronization input, FSI, is checked on the falling edge of the SCO signal. If the FSI line is low, then the first data bit on the serial data in (SDI) line is latched in on the next SCO falling edge.

Set the active edge of the FSI signal to occur at a position when the SCO signal is high or low to allow setup and hold times from the SCO falling edge to be met. The width of the FSI signal can be set to between 1 and 32 SCO periods wide. A second, or subsequent, falling edge that occurs before 32 SCO periods elapses is ignored.

Figure 3 details the format for the serial data being written to the AD7764 through the SDI pin. Thirty-two bits are required for a write operation. The first 16 bits select the register address that the data being read is intended for. The second 16 bits contain the data for the selected register.

Writing to the AD7764 is allowed at any time, even while reading a conversion result. Note that, after writing to the device, valid data is not output until after the settling time for the filter elapses. The FILTER\_SETTLE status bit is asserted at this point to indicate that the filter has settled and that valid data is available at the output.

## FUNCTIONALITY

### SYNCHRONIZATION

The  $\overline{\text{SYNC}}$  input to the AD7764 provides a synchronization function that allows the user to begin gathering samples of the analog front-end input from a known point in time.

The  $\overline{\text{SYNC}}$  function allows multiple AD7764 devices, operated from the same master clock that use common  $\overline{\text{SYNC}}$  and  $\overline{\text{RESET}}$  signals, to be synchronized so that each ADC simultaneously updates its output register. Note that all devices being synchronized must operate in the same power mode and at the same decimation rate.

In the case of a system with multiple AD7764 devices, connect common MCLK,  $\overline{\text{SYNC}}$  and  $\overline{\text{RESET}}$  signals to each AD7764.

The AD7764  $\overline{\text{SYNC}}$  pin is polled by the falling edge of MCLK. The AD7764 device goes into  $\overline{\text{SYNC}}$  when an MCLK falling edge senses that the  $\overline{\text{SYNC}}$  input signal is logic low. At this point, the digital filter sequencer is reset to 0. The filter is held in a reset state (in  $\overline{\text{SYNC}}$  mode) until the first MCLK falling edge senses  $\overline{\text{SYNC}}$  to be logic high

Where possible, ensure that all transitions of  $\overline{\text{SYNC}}$  occur synchronously with the rising edge of MCLK (that is, as far away as possible from the MCLK falling edge, or decision edge). Otherwise, abide by the timing specified in Figure 43, which excludes the  $\overline{\text{SYNC}}$  rising edge from occurring in a 10 ns window centered around the MCLK fallings edge.

Keep  $\overline{\text{SYNC}}$  logic low for a minimum of four MCLK periods. When the MCLK falling edge senses that  $\overline{\text{SYNC}}$  has returned to logic high, the AD7764 filters begin to gather input samples simultaneously. The FSO falling edges are also synchronized, allowing for simultaneous output of conversion data.

Figure 43.  $\overline{\text{SYNC}}$  Timing Relative to MCLK

Following a  $\overline{\text{SYNC}}$  pulse, the digital filter needs time to settle before valid data can be read from the AD7764. To ensure there is valid data on the SDO line, by check the FILTER\_SETTLE status bit (see D7 in Table 12) that is output with each conversion result. The time from the rising edge of  $\overline{\text{SYNC}}$  until the FILTER\_SETTLE bit asserts depends on the filter configuration used. See the Theory of Operation section and the values listed in Table 8 and Table 9 for details on calculating the time until FILTER\_SETTLE asserts. Note that the FILTER\_SETTLE bit is designed as a reactionary flag to indicate when the conversion data output is valid.

### OVERRANGE ALERTS

The AD7764 offers an overrange function in both a pin and status bit output. The overrange alerts indicate when the voltage applied to the AD7764 modulator input pins exceeds the limit set in the overrange register, indicating that the voltage applied is approaching a level that places the modulator in an overrange condition. To set this limit, the user must program the register. The default overrange limit is set to 80% of the  $V_{\text{REF}}$  voltage (see the AD7764 Registers section).

The OVERRANGE pin outputs logic high to alert the user that the modulator has sampled an input voltage greater in magnitude than the overrange limit as set in the overrange register. The OVERRANGE pin is set to logic high when the modulator samples an input above the overrange limit. After the input returns below the limit, the OVERRANGE pin returns to zero. The OVERRANGE pin is updated after the first FIR filter stage. The output of OVERRANGE changes at the ICLK/4 frequency.

The OVR status bit is output as Bit D6 on SDO during a data conversion and can be checked in the AD7764 status register. This bit is less dynamic than the OVERRANGE pin output. It is updated on each conversion result output; that is, the bit changes at the output data rate. If the modulator samples a voltage input that exceeds the overrange limit during the process of gathering samples for a particular conversion result output, then the OVR bit is set to logic high.

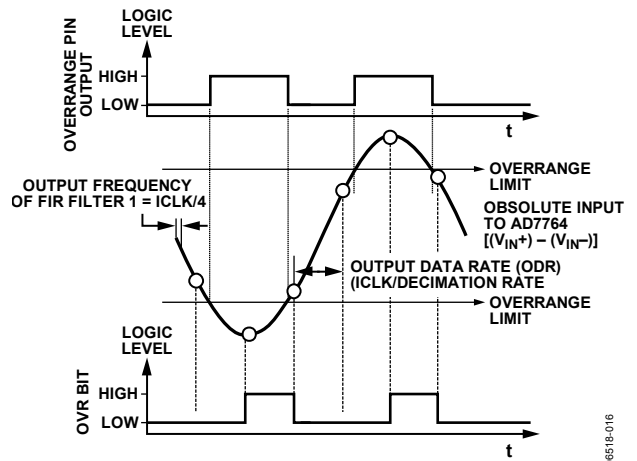

Figure 44. OVERRANGE Pin and OVR Bit vs. Absolute Voltage Applied to the Modulator

The output points from FIR Filter 1 in Figure 44 are not drawn to scale relative to the output data rate points. The FIR Filter 1 output is updated either 16x, 32x, or 64x faster than the output data rate, depending on the decimation rate in operation.

## POWER MODES

### Low Power Mode

During power-up, the AD7764 defaults to operate in normal power mode. There is no register write required.

The AD7764 also offers low power mode. To operate the device in low power mode, set the LPWR bit in the control register to logic high (see Figure 45). Operating the AD7764 in low power mode has no impact on the output data rate or available bandwidth.

Figure 45. Write Scheme for Low Power Mode

### RESET/PWRDWN Mode

The AD7764 features a  $\overline{\text{RESET/PWRDWN}}$  pin. Holding the input to this pin logic low places the AD7764 in power-down mode. All internal circuitry is reset. Apply a  $\overline{\text{RESET}}$  pulse to the AD7764 after initial power-up of the device.

The AD7764  $\overline{\text{RESET}}$  pin is polled by the rising edge of MCLK. The AD7764 device goes into reset when an MCLK rising edge senses the  $\overline{\text{RESET}}$  input signal to be logic low. AD7764 comes out of  $\overline{\text{RESET}}$  on the first MCLK rising edge that senses  $\overline{\text{RESET}}$  to be logic high.

The best practice is to ensure that all transitions of  $\overline{\text{RESET}}$  occur synchronously with the falling edge of MCLK; otherwise, adhere to the timing requirements shown in Figure 46.

Keep  $\overline{\text{RESET}}$  at logic low for a minimum of one MCLK period for a valid reset to occur.

In cases where multiple AD7764 devices are being synchronized using the SYNC pulse and in the case of daisy-chaining multiple AD7764 devices, a common  $\overline{\text{RESET}}$  pulse must be provided in addition to the common SYNC and MCLK signals.

Figure 46.  $\overline{\text{RESET}}$  Timing Synchronous to MCLK

## DECIMATION RATE PIN

The decimation rate of the AD7764 is selected using the DEC\_RATE pin. Table 14 shows the voltage input settings required for each of the three decimation rates.

Table 14. DEC\_RATE Pin Settings

Decimation Rate	DEC_RATE Pin State	Maximum ODR (kHz)
64x	DV <sub>DD</sub>	312.5
128x	Floating	156.25
256x	Ground	78.125

## DAISY-CHAINING

Daisy-chaining allows numerous devices to use the same digital interface lines. This feature is especially useful for reducing component count and wiring connections, such as in isolated multiconverter applications or for systems with a limited interfacing capacity. Data readback is analogous to clocking a shift register. When daisy-chaining is used, all devices in the chain must operate in a common power mode and at a common decimation rate.

The block diagram in Figure 47 shows how to connect devices to achieve daisy-chain functionality. Figure 47 shows four AD7764 devices daisy-chained together with a common MCLK signal applied. This configuration works in decimate 128× or decimate 256× mode only.

### READING DATA IN DAISY-CHAIN MODE

Referring to Figure 47, note that the SDO line of AD7764 (A) provides the output data from the chain of AD7764 converters. Also, note that for the last device in the chain, AD7764 (D), the SDI pin is connected to ground. All of the devices in the chain must use common MCLK and SYNC signals.

To enable the daisy-chain conversion process, apply a common SYNC pulse to all devices (see the Synchronization section).

After a SYNC pulse is applied to all devices, the filter settling time must pass before the FILTER\_SETTLE bit is asserted, indicating valid conversion data at the output of the chain of devices. As shown in Figure 48, the first conversion result is output from the device labeled AD7764 (A).

This 32-bit conversion result is then followed by the conversion results from the AD7764 (B), AD7764 (C), and AD7764 (D) devices with all conversion results output in an MSB-first sequence. The signals output from the daisy chain are the stream of conversion results from the SDO pin of AD7764 (A) and the FSO signal output by the first device in the chain, AD7764 (A).

The falling edge of FSO signals the MSB of the first conversion output in the chain. FSO stays logic low throughout the 32 SCO clock periods needed to output the AD7764 (A) result and then goes logic high during the output of the conversion results from the AD7764 (B), AD7764 (C), and AD7764 (D) devices.

The maximum number of devices that can be daisy-chained is dependent on the decimation rate selected. Calculate the maximum number of devices that can be daisy-chained by simply dividing the chosen decimation rate by 32 (the number of bits that must be clocked out for each conversion). Table 15 provides the maximum number of chained devices for each decimation rate.

**Table 15. Maximum Daisy Chain Length for all Decimation Rates**

Decimation Rate	Maximum Chain Length
256×	8 devices
128×	4 devices
64×	2 devices

Figure 47. Daisy-Chaining Four Devices in Decimate 128× Mode Using a 40 MHz MCLK Signal

Figure 48. Daisy-Chain Mode, Data Read Timing Diagram (for the Daisy-Chain Configuration Shown in Figure 47)

**WRITING DATA IN DAISY-CHAIN MODE**

Writing to AD7764 devices in daisy-chain mode is similar to writing to a single device. The serial writing operation is synchronous to the SCO signal. The status of the frame synchronization input,  $\overline{\text{FSI}}$ , is checked on the falling edge of the SCO signal. If the  $\overline{\text{FSI}}$  line is low, then the first data bit on the serial data in the SDI line is latched in on the next SCO falling edge.

Writing data to the AD7764 in daisy-chain mode operates with the same timing structure as writing to a single device (see Figure 3). The difference between writing to a single device and writing to a number of daisy-chained devices is in the implementation of the  $\overline{\text{FSI}}$  signal. The number of devices that are in the daisy chain determines the period for which the  $\overline{\text{FSI}}$  signal must remain logic low. To write to n number of devices in the daisy chain, the period between the falling edge of  $\overline{\text{FSI}}$  and the rising edge of  $\overline{\text{FSI}}$  must

be between  $32 \times (n - 1)$  to  $32 \times n$  SCO periods. For example, if three AD7764 devices are being written to in daisy-chain mode,  $\overline{\text{FSI}}$  is logic low for between  $32 \times (3 - 1)$  to  $32 \times 3$  SCO pulses. This means that the rising edge of  $\overline{\text{FSI}}$  must occur between the 64<sup>th</sup> and 96<sup>th</sup> SCO periods.

The AD7764 devices can be written to at any time. The falling edge of  $\overline{\text{FSI}}$  overrides all attempts to read data from the SDO pin. In the case of a daisy chain, the  $\overline{\text{FSI}}$  signal remaining logic low for more than 32 SCO periods indicates to the AD7764 device that there are more devices further on in the chain. This means that the AD7764 directs data that is input on the SDI pin to its SDO pin. This ensures that data is passed to the next device in the chain.

Figure 49. Writing to an AD7764 Daisy-Chain Configuration

Figure 50. Daisy-Chain Write Timing Diagram; Writing to Four AD7764 Devices

## CLOCKING THE AD7764

The AD7764 requires an external low jitter clock source. This signal is applied to the MCLK pin. An internal clock signal (ICLK) is derived from the MCLK input signal. The ICLK controls the internal operation of the AD7764. The maximum ICLK frequency is 20 MHz. To generate the ICLK,

$$ICLK = MCLK/2$$

For output data rates equal to those used in audio systems, a 12.288 MHz ICLK frequency can be used. As shown in Table 6, output data rates of 96 kHz and 48 kHz are achievable with this ICLK frequency.

### MCLK JITTER REQUIREMENTS

The MCLK jitter requirements depend on a number of factors and are given by

$$t_{j(rms)} = \frac{\sqrt{OSR}}{2 \times \pi \times f_{IN} \times 10 \frac{SNR(dB)}{20}}$$

where:

OSR (the oversampling ratio) =  $f_{CLK}/ODR$ .

$f_{IN}$  is the maximum input frequency.

SNR(dB) is the target SNR.

#### Example 1

Take Example 1 from Table 6, where

ODR = 312.5 kHz.

$f_{CLK}$  = 20 MHz.

$f_{IN}$  (max) = 156.25 kHz.

SNR = 104 dB.

$$t_{j(rms)} = \frac{\sqrt{64}}{2 \times \pi \times 156.25 \times 10^3 \times 10^{5.2}} = 51.41 \text{ ps}$$

This is the maximum allowable clock jitter for a full-scale, 156.25 kHz input tone with the given ICLK and output data rate.

#### Example 2

Take Example 2 from Table 6, where

ODR = 48 kHz.

$f_{CLK}$  = 12.288 MHz.

$f_{IN}$  (max) = 19.2 kHz.

SNR = 109 dB.

$$t_{j(rms)} = \frac{\sqrt{256}}{2 \times \pi \times 19.2 \times 10^3 \times 10^{5.45}} = 470 \text{ ps}$$

The input amplitude also has an effect on these jitter figures. For example, if the input level is 3 dB below full scale, the allowable jitter is increased by a factor of  $\sqrt{2}$ , increasing the first example to 144.65 ps rms. This happens when the maximum slew rate is decreased by a reduction in amplitude.

Figure 51 and Figure 52 illustrate this point, showing the maximum slew rate of a sine wave of the same frequency but with different amplitudes.

Figure 51. Maximum Slew Rate of a Sine Wave with an Amplitude of 2 V p-p

Figure 52. Maximum Slew Rate of the Same Frequency Sine Wave as in Figure 51 with an Amplitude of 1 V p-p

## DECOUPLING AND LAYOUT INFORMATION

### SUPPLY DECOUPLING

The decoupling of the supplies applied to the [AD7764](#) is important in achieving maximum performance. Each supply pin must be decoupled to the correct ground pin with a 100 nF, 0603 case size capacitor.

Pay particular attention to decoupling Pin 7 ( $AV_{DD2}$ ) directly to the nearest ground pin (Pin 8). The digital ground pin, AGND2 (Pin 20), is routed directly to ground. Also, connect REFGND (Pin 26) directly to ground.

Decouple the  $DV_{DD}$  (Pin 17) and  $AV_{DD3}$  (Pin 28) supplies to the ground plane at a point away from the device.

It is recommended to decouple the supplies that are connected to the following supply pins through 0603 size, 100 nF capacitors to a star ground point linked to Pin 23 (AGND1):

- $V_{REF+}$  (Pin 27)
- $AV_{DD4}$  (Pin 25)
- $AV_{DD1}$  (Pin 24)
- $AV_{DD2}$  (Pin 21)

A layout decoupling scheme for these supplies, which connect to the right side of the [AD7764](#), is shown in Figure 53. Note the star point ground created at Pin 23.

Figure 53. Supply Decoupling

### REFERENCE VOLTAGE FILTERING

A low noise reference source, such as the [ADR444](#) or [ADR434](#) (4.096 V), is suitable for use with the [AD7764](#). Decouple and filter the reference voltage supplied to the [AD7764](#) as shown in Figure 54.

The recommended scheme for the reference voltage supply is a 200  $\Omega$  series resistor connected to a 100  $\mu\text{F}$  tantalum capacitor, followed by a 10 nF decoupling capacitor very close to the  $V_{REF+}$  pin.

Figure 54. Reference Connection

### DIFFERENTIAL AMPLIFIER COMPONENTS

The components recommended for use around the on-chip differential amplifier are detailed in Table 10. Matching the components on both sides of the differential amplifier is important to minimize distortion of the signal applied to the amplifier. A tolerance of 0.1% or better is required for these components. Symmetrical routing of the tracks on both sides of the differential amplifier also assists in achieving the stated performance. Figure 55 shows a typical layout for the components around the differential amplifier. Note that the traces for both differential paths are as symmetrical as possible and that the feedback resistors and capacitors are placed on the underside of the PCB to enable the simplest routing.

Figure 55. Typical Layout Structure for Components Surrounding the Differential Amplifier

### LAYOUT CONSIDERATIONS

The use of correct components is essential to achieve optimum performance, and the correct layout is equally important. The [AD7764](#) product page contains the Gerber files for the [AD7764](#) evaluation board. Use the Gerber files as a reference when designing any system using the [AD7764](#).

Carefully consider the use of ground planes. To ensure that the return currents through the decoupling capacitors are flowing to the correct ground pin, place the ground side of the capacitors as close as possible to the ground pin associated with that supply, as recommended in the Supply Decoupling section.

### USING THE AD7764

Use the following sequence to power up and use the [AD7764](#):

1. Apply power to the device.
2. Apply the MCLK signal.
3. Take RESET low for a minimum of one MCLK cycle, preferably synchronous to the falling MCLK edge. If multiple devices are to be synchronized, apply a common RESET to all devices.
4. Wait a minimum of two MCLK cycles after RESET is released.
5. If multiple devices are being synchronized, a SYNC pulse must be applied to the devices, preferably synchronous with the MCLK rising edge. In the case where devices are not being synchronized, no SYNC pulse is required; apply a logic high signal to the SYNC pin.

When applying the SYNC pulse,

- The issue of a SYNC pulse to the device must not coincide with a write to the device.
- Ensure that the SYNC pulse is taken low for a minimum of four MCLK periods.

Data can then be read from the device using the default gain and overrange threshold values. The conversion data read is not valid, however, until the settling time of the filter elapses. After this time elapses, the FILTER\_SETTLE status bit is set, indicating that the data is valid.

Values for the gain and overrange thresholds can be written to or read from the respective registers at this stage.

### BIAS RESISTOR SELECTION

The [AD7764](#) requires a resistor to be connected between the R<sub>BIAS</sub> and AGND<sub>x</sub> pins. Select the resistor value to give a current of 25  $\mu$ A through the resistor to ground. For a 4.096 V reference voltage, the correct resistor value is 160 k $\Omega$ .

## AD7764 REGISTERS

The AD7764 has a number of user-programmable registers. The control register sets the functionality of the on-chip buffer and differential amplifier and provides the option to power down the AD7764. There are also digital gain and overrange threshold

registers. Writing to these registers involves writing the register address followed by a 16-bit data-word. The register addresses, details of the individual bits, and default values are provided in the following sections.

### CONTROL REGISTER

Table 16. Control Register (Address 0x0001, Default Value 0x0000)

MSB														LSB	
D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
0	RD OVR	RD GAIN	0	RD STAT	0	SYNC	0	BYPASS REF	0	0	0	PWR DOWN	LPWR	REF BUF OFF	AMP OFF

Table 17. Bit Descriptions of the Control Register

Bit	Mnemonic	Description
14	RD OVR <sup>1,2</sup>	Read overrange. If this bit is set, the next read operation outputs the contents of the overrange threshold register instead of a conversion result.
13	RD GAIN <sup>2</sup>	Read gain. If this bit is set, the next read operation outputs the contents of the digital gain register.
11	RD STAT <sup>2</sup>	Read status. If this bit is set, the next read operation outputs the contents of the status register.
9	SYNC <sup>1</sup>	Synchronize. Setting this bit initiates an internal synchronization routine. Setting this bit simultaneously on multiple devices synchronizes all filters.
7	BYPASS REF	Bypass reference. Setting this bit bypasses the reference buffer if the buffer is off.
3	PWR DOWN	Power-down. A logic high powers the device down without resetting. Writing a 0 to this bit powers the device back up.
2	LPWR	Low power mode. Set this bit to Logic 1 when the AD7764 is in low power mode.
1	REF BUF OFF	Reference buffer off. Asserting this bit powers down the reference buffer.
0	AMP OFF	Amplifier off. Asserting this bit switches the differential amplifier off.

<sup>1</sup> Bit 14 to Bit 11 and Bit 9 are self-clearing bits.

<sup>2</sup> Only one of the bits from D14 to D11 can be set in any write operation. The user must select only one function from these bits. That bit, one of Bit D14 to D11, read determines the contents of the data output within the next FSO frame on the SDO pin.

### STATUS REGISTER

Table 18. Status Register (Read Only)

MSB														LSB	
D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
PARTNO	1	0	0	1	FILTER_SETTLE	LPWR	OVR	0	1	0	REF BUF OFF	AMP OFF	0	DEC 1	DEC 0

Table 19. Bit Descriptions of the Status Register

Bits	Mnemonic	Description
15	PARTNO	Part number. This bit is set to 1 for the AD7764.
10	FILTER_SETTLE	Filter settling bit. This bit corresponds to the FILTER_SETTLE bit in the status word output in the second 16-bit read operation. It indicates when data is valid.
9	LPWR	Low power mode. This bit is set when operating in low power mode.
8	OVR	Overrange. If the current analog input exceeds the current overrange threshold, this bit is set.
4	REF BUF OFF	Reference buffer off. This bit is set when the reference buffer is disabled.
3	AMP OFF	Amplifier off. This bit is set when the input amplifier is disabled.
2	0	Zero. This bit is set to Logic 0.
1	DEC_RATE 1	Decimation rate. This bit corresponds to the decimation rate in use.
0	DEC_RATE 0	Decimation rate. This bit corresponds to the decimation rate in use.

**GAIN REGISTER—ADDRESS 0x0004*****Nonbit Mapped, Default Value: 0xA000***

The gain register is scaled such that 0x8000 corresponds to a gain of 1.0. The default value of this register is 1.25 (0xA000). This value results in a full-scale digital output when the input is at 80% of  $V_{REF+}$ , tying in with the maximum analog input range of  $\pm 80\%$  of  $V_{REF+}$  p-p.

**OVERRANGE REGISTER—ADDRESS 0x0005*****Nonbit Mapped, Default Value: 0xCCCC***

The overrange register value is compared to the output of the first decimation filter to obtain an overload indication with minimum propagation delay. This comparison is prior to any gain scaling. The default value is 0xCCCC, which corresponds to 80% of  $V_{REF+}$  (the maximum permitted analog input voltage). Assuming  $V_{REF+} = 4.096$  V, the bit is then set when the input voltage exceeds approximately 6.55 V p-p differential. The overrange bit is set immediately if the analog input voltage exceeds 100% of  $V_{REF+}$  for more than four consecutive samples at the modulator rate.
