## feATURES

- 1ppm Linearity with No Missing Codes
- Integrated Amplifier for Direct Sensor Digitization
- 2 Differential or 4 Single-Ended Input Channels
- Up to 8kHz Output Rate (External fo)
- Up to 4kHz Multiplexing Rate (External $\mathrm{f}_{0}$ )
- Selectable Speed/Resolution

## $2.1 \mu \mathrm{~V}_{\text {RMS }}$ Noise at 1.76 kHz Output Rate $220 n V_{\text {RMS }}$ Noise at 13.8 Hz Output Rate with Simultaneous 50Hz/60Hz Rejection

- Guaranteed Modulator Stability and Lock-Up Immunity for any Input and Reference Conditions
- $<5 \mu \mathrm{~V}$ Offset ( $4.5 \mathrm{~V}<\mathrm{V}_{\mathrm{CC}}<5.5 \mathrm{~V},-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$ )
- Differential Input and Differential Reference with GND to $V_{C C}$ Common Mode Range
- No Latency Mode, Each Conversion is Accurate Even After a New Channel is Selected
- Internal Oscillator-No External Components
- 36-Lead SSOP Package

## APPLICATIONS

- Auto Ranging 6-Digit DVMs
- High Speed Multiplexing
- Weight Scales
- Direct Temperature Measurement
- High Speed Data Acquisition

24-Bit High Speed 4-Channel $\Delta \Sigma$ ADC with Integrated Amplifier DESCRIPTION

The LTC ${ }^{\circledR} 2442$ is an ultra high precision, variable speed, 24 -bit $\Delta \Sigma^{\text {me }}$ ADC with integrated amplifier. The amplifier can be configured as a buffer for easy input drive of high impedance sensors. 1 part-per-million (ppm) linearity is achievable when the amplifier is configured in unity gain. External resistors can be used to set a gain for increased resolution of low level input signals. The positive and negative amplifier supply pins may be tied directly to $\mathrm{V}_{\mathrm{CC}}$ (4.5V to 5.5 V ) and GND or biased above $\mathrm{V}_{\mathrm{CC}}$ and below GND for rail-to-rail input signals.

The proprietary $\Delta \Sigma$ architecture ensures stable DC accuracy through continuous transparent calibration. Ten speed/resolution combinations from $6.9 \mathrm{~Hz} / 220 \mathrm{nV} \mathrm{V}_{\text {RMS }}$ to $3.5 \mathrm{kHz} / 25 \mu \mathrm{~V}_{\text {RMS }}$ can be selected with no latency or shift in DC accuracy. Additionally, a 2X speed mode can be selected enabling output rates up to $7 \mathrm{kHz}(8 \mathrm{kHz}$ with an external oscillator) with one cycle latency.

Any combination of single-ended (up to 4 inputs) or differential (up to 2 inputs) can be selected with a common mode input range from ground to $\mathrm{V}_{\text {CC }}$. While operating in the 1X speed mode the first conversion following a new speed/resolution or channel selection is valid.

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.
Note 2: All voltage values are with respect to GND.
Note 3: $\mathrm{V}_{\mathrm{CC}}=4.5 \mathrm{~V}$ to 5.5 V unless otherwise specified.
$V_{\text {REF }}=$ REF $^{+}-$REF $^{-}, V_{\text {REECM }}=\left(\right.$ REF $^{+}+$REF $\left.^{-}\right) / 2$;
$\mathrm{V}_{\mathrm{IN}}=$ SEL $^{+}-$SEL-$^{-}, \mathrm{V}_{\text {INCM }}=\left(\right.$ SEL $^{+}+$SELL $\left.^{-}\right) / 2$.
Note 4: Fo pin tied to GND or to external conversion clock source with
$\mathrm{f}_{\text {EOSC }}=10 \mathrm{MHz}$ unless otherwise specified.
Note 5: Guaranteed by design, not subject to test.
Note 6: Integral nonlinearity is defined as the deviation of a code from a straight line passing through the actual endpoints of the transfer curve. The deviation is measured from the center of the quantization band.
Note 7 : The converter uses the internal oscillator.

Note 8: The converter is in external SCK mode of operation such that the SCK pin is used as a digital input. The frequency of the clock signal driving SCK during the data output is f ESCK and is expressed in Hz .
Note 9: The converter is in internal SCK mode of operation such that the SCK pin is used as a digital output. In this mode of operation, the SCK pin has a total equivalent load capacitance of $\mathrm{C}_{\text {LOAD }}=20 \mathrm{pF}$.
Note 10: The external oscillator is connected to the $\mathrm{F}_{0}$ pin. The external oscillator frequency, f Eosc, is expressed in Hz .
Note 11: The converter uses the internal oscillator. $\mathrm{F}_{0}=\mathrm{OV}$.
Note 12: Guaranteed by design and test correlation.
Note 13: There is an internal reset that adds an additional 5 to $15 \mathrm{f}_{0}$ cycles to the conversion time.
Note 14: In order to achieve optimum linearity, the amplifier power positive supply input ( $\mathrm{V}^{+}$) must exceed the maximum input voltage level by 2 V or greater. The negative amplifier power supply input ( $\mathrm{V}^{-}$) must be at least 200 mV below the minimum input voltage level.
Note 15: Amplifiers are externally compensated with 0.1 HF .

## PIn fUnCTIOnS

SCK (Pin1): Bidirectional Digital Clock Pin. In internal serial clock operation mode, SCK is used as a digital output for the internal serial interface clock during the data output period. In the external serial clock operation mode, SCK is used as the digital input for the external serial interface clock during the data output period. The serial clock operation mode is determined by the logic level applied to EXT (Pin 3).
BUSY (Pin 2): Conversion in Progress Indicator. This pin is HIGH while the conversion is in progress and goes LOW indicating the conversion is complete and data is ready. It remains LOW during the sleep and data output states. At the conclusion of the data output state, it goes HIGH indicating a new conversion has begun.
EXT (Pin 3): Internal/External SCK Selection Pin. This pin is used to select internal or external SCK for outputting/ inputting data. If EXT is tied low, the device is in the external SCK mode and data is shifted out of the device under the control of a user applied serial clock. If EXT is tied high, the internal serial clock mode is selected. The device generates its own SCK signal and outputs this on the SCK pin. A framing signal BUSY (Pin 2) goes low indicating data is being output.

GND (Pins 4, 5, 32): Ground. Multiple ground pins internally connected for optimum ground current flow and $V_{C C}$ decoupling. Connect each one of these pins to a common ground plane through a low impedance connection. All three pins must be connected to ground for proper operation.
CHO to CH3 (Pins 6, 7, 8, 9): Analog Inputs. May be programmed for single-ended or differential mode. (See Table 3)
ADCINB (Pin 10): ADC Input. Must tie to the amplifier output, OUTB (Pin 17).
ADCINA (Pin 11): ADC Input. Must tie to the amplifier output, OUTA (Pin 12).
OUTA (Pin 12): Amplifier A output. Must be compensated with $0.1 \mu \mathrm{~F}$ or greater capacitor. Drives the ADCINA ADC input (Pin 11).
-INA (Pin 13): Amplifier A negative Input. By shorting this pin to OUTA (Pin 12) the amplifier becomes a buffer with unity gain. Alternatively, an external resistor network may be added here for gains greater than 1.

NC (Pins 14, 15, 16, 20, 22, 23): No Connect. These pins should be left floating or tied to Ground.
OUTB (Pin 17): Amplifier B Output. Must be compensated with $0.1 \mu \mathrm{~F}$ or greater capacitor. Drives the ADCINB ADC input (Pin 10).
-INB (Pin 18): Amplifier B negative Input. By shorting this pin to OUTB (Pin 17) the amplifier becomes a buffer with unity gain. Alternatively, an external resistor network may be added here for gains greater than 1.
+INB (Pin 19): Amplifier B positive Input. Must tie to the Multiplexer output MUXOUTB (Pin 26).
$\mathbf{V}^{+}$(Pin 21): Amplifier positive supply voltage input. May tie to $\mathrm{V}_{\text {CC }}$ or an external supply voltage up to 15 V . Bypass to GND with $1 \mu \mathrm{~F}$ capacitor.
$\mathbf{V}^{-}$(Pin 24): Amplifier Negative supply voltage input. May tie to GND or an external supply voltage as low as -15 V . Bypass to GND with a $1 \mu \mathrm{~F}$ capacitor.
+INA (Pin 25): Amplifier A positive Input. Must tie to the Multiplexer output MUXOUTA (Pin 27).
MUXOUTB (Pin 26): Multiplexer Output. Must tie to +INB amplifier input (Pin 19).

MUXOUTA (Pin 27): Multiplexer Output. Must tie to +INA amplifier input (Pin 25).
COM (Pin 28): The common negative input (SEL-$)$ for all single ended multiplexer configurations. The voltage on $\mathrm{CHO}-\mathrm{CH} 3$ and COM pins can have any value between GND -0.3 V to $\mathrm{V}_{\mathrm{CC}}+0.3 \mathrm{~V}$. Within these limits, the two selected inputs (SEL+ and SEL ${ }^{-}$) provide a bipolar input range ( $\mathrm{V}_{\mathrm{IN}}$ $=$ SEL $^{+}-$SEL $^{-}$) from $-0.5 \cdot \mathrm{~V}_{\text {REF }}$ to $0.5 \cdot \mathrm{~V}_{\text {REF }}$. Outside this input range, the converter produces unique over-range and under-range output codes.

## PIn functions

Vcc (Pin 29): Positive Supply Voltage. Bypass to GND with a $10 \mu \mathrm{~F}$ tantalum capacitor in parallel with a $0.1 \mu \mathrm{~F}$ ceramic capacitor as close to the part as possible.
REF+ (Pin 30), REF-(Pin 31): Differential Reference Input. The voltage on these pins can have any value between GND and $\mathrm{V}_{\mathrm{CC}}$ as long as the reference positive input, $\mathrm{REF}^{+}$, is maintained more positive than the negative reference input, REF- , by at least 0.1 V . Bypass to GND with $0.1 \mu \mathrm{~F}$ Ceramic capacitor as close to the part as possible.

SDI (Pin 33): Serial Data Input. This pin is used to select the speed, 1 X or 2 X mode, resolution and input channel for the next conversion cycle. At initial power up, the default mode of operation is $\mathrm{CHO}-\mathrm{CH} 1, ~ O S R$ of 256 and 1X mode. The serial data input contains an enable bit which determines if a new channel/speed is selected. If this bit is low the following conversion remains at the same speed and selected channel. The serial data input is applied to the device under control of the serial clock (SCK) during the data output cycle. The first conversion following a new channel/speed is valid.
$\mathrm{F}_{0}$ (Pin 34): Frequency Control Pin. Digital input that controls the internal conversion clock. When $F_{0}$ is connected to $\mathrm{V}_{\mathrm{CC}}$ or GND, the converter uses its internal oscillator.
CS (Pin 35): Active Low Chip Select. A LOW on this pin enables the SDO digital output and wakes up the ADC. Following each conversion the ADC automatically enters the sleep mode and remains in this state as long as $\overline{\mathrm{CS}}$ is HIGH. A LOW-to-HIGH transition on $\overline{\mathrm{CS}}$ during the Data Output aborts the data transfer and starts a new conversion.

SDO (Pin 36): Three-State Digital Output. During the data output period, this pin is used as serial data output. When the chip select $\overline{C S}$ is HIGH ( $\overline{C S}=V_{C C}$ ) the SDO pin is in a high impedance state. During the conversion and sleep periods, this pin is used as the conversion status output. The conversion status can be observed by pulling $\overline{\mathrm{CS}} \mathrm{LOW}$. This signal is HIGH while the conversion is in progress and goes LOW once the conversion is complete.

## APPLICATIONS INFORMATION

CONVERTER OPERATION

## Converter Operation Cycle

The LTC2442 is a multi-channel, high speed, $\Delta \Sigma$ ana-log-to-digital converter with an easy to use 3 - or 4 -wire serial interface (see Figure 1). Its operation is made up of three states. The converter operating cycle begins with the conversion, followed by the sleep state and ends with the data output/input (see Figure 2). The 4-wire interface consists of serial data input (SDI), serial data output (SDO), serial clock (SCK) and chip select ( $\overline{\mathrm{CS}}$ ). The interface, timing, operation cycle and data out format is compatible with Linear's entire family of $\Delta \Sigma$ converters.
Initially, the LTC2442 performs a conversion. Once the conversion is complete, the device enters the sleep state. The part remains in the sleep state as long as $\overline{\mathrm{CS}}$ is HIGH. The conversion result is held indefinitely in a static shift register while the converter is in the sleep state.

Once $\overline{\mathrm{CS}}$ is pulled LOW, the device begins outputting the conversion result. There is no latency in the conversion result while operating in the 1 X mode. The data output corresponds to the conversion just performed. This re-

Figure 2. LTC2442 State Transition Diagram

## APPLICATIONS InFORMATION

sult is shifted out on the serial data out pin (SDO) under the control of the serial clock (SCK). Data is updated on the falling edge of SCK allowing the user to reliably latch data on the rising edge of SCK (see Figure 3). The data output state is concluded once 32 bits are read out of the ADC or when $\overline{\mathrm{CS}}$ is brought HIGH. In either scenario, the device automatically initiates a new conversion and the cycle repeats.

Through timing control of the $\overline{\mathrm{CS}}, \mathrm{SCK}$ and $\overline{\mathrm{EXT}}$ pins, the LTC2442 offers several flexible modes of operation (internal or external SCK). These various modes do not require programming configuration registers; moreover, they do not disturb the cyclic operation described above. These modes of operation are described in detail in the Serial Interface Timing Modes section.

## Ease of Use

The LTC2442 data output has no latency, filter settling delay or redundant data associated with the conversion cycle while operating in the 1 X mode. There is a one-to-one correspondence between the conversion and the output data. Therefore, multiplexing multiple analog voltages is easy. Speed/resolution adjustments may be made seamlessly between two conversions without settling errors.

The LTC2442 performs offset and full-scale calibrations every conversion cycle. This calibration is transparent to the user and has no effect on the cyclic operation described above. The advantage of continuous calibration is extreme stability of offset and full-scale readings with respect to time, supply voltage change and temperature drift.

## Power-Up Sequence

The LTC2442 automatically enters an internal reset state when the power supply voltage $\mathrm{V}_{\text {CC }}$ drops below approximately 2.2 V . This feature guarantees the integrity of the conversion result and of the serial interface mode selection.

When the $\mathrm{V}_{\text {CC }}$ voltage rises above this critical threshold, the converter creates an internal power-on-reset (POR) signal with a duration of approximately 0.5 ms . The POR signal clears all internal registers. The conversion immediately following a POR is performed on the input channel SEL+ = $\mathrm{CH} 0, \mathrm{SEL}^{-}=\mathrm{CH} 1$ at an $\mathrm{OSR}=256$ in the 1X mode. Following the POR signal, the LTC2442 starts a normal conversion cycle and follows the succession of states described above. The first conversion result following POR is accurate within the specifications of the device if the power supply voltage is restored within the operating range ( 4.5 V to 5.5 V ) before the end of the POR time interval.

Figure 3. SDI Speed/Resolution, Channel Selection, and Data Output Timing

## APPLICATIONS INFORMATION

## Reference Voltage Range

The LTC2442 $\Delta \Sigma$ converter accepts a truly differential external reference voltage. The absolute/common mode voltage specification for the REF+ and REF ${ }^{-}$pins covers the entire range from GND to $\mathrm{V}_{\mathrm{CC}}$. For correct converter operation, the REF $^{+}$pin must always be more positive than the REF ${ }^{-}$pin.
The LTC2442 can accept a differential reference voltage from 0.1 V to $\mathrm{V}_{\mathrm{Cc}}$. The converter output noise is determined by the thermal noise of the front-end circuits, and as such, its value in microvolts is nearly constant with reference voltage. A decrease in reference voltage will not significantly improve the converter's effective resolution. On the other hand, a reduced reference voltage will improve the converter's overall INL performance.

## Input Voltage Range

Refer to Figure 24. The analog input is truly differential with an absolute/common mode range for the CHO 0 CH 3 and COM input pins extending from GND -0.3 V to $\mathrm{V}_{\text {CC }}$ +0.3 V . Outside these limits, the ESD protection devices begin to turn on and the errors due to input leakage current increase rapidly. Withinthese limits, the LTC2442 converts the bipolar differential input signal, $\mathrm{V}_{\mathrm{IN}}=\mathrm{SEL}^{+}-\mathrm{SEL}^{-}$, from $-\mathrm{FS}=-0.5 \cdot \mathrm{~V}_{\text {REF }}$ to $+\mathrm{FS}=0.5 \cdot \mathrm{~V}_{\text {REF }}$ where $\mathrm{V}_{\text {REF }}=$ REF ${ }^{+}$- REF ${ }^{-}$. Outside this range, the converter indicates the overrange or the underrange condition using distinct output codes.

## Output Data Format

The LTC2442 serial output data stream is 32 bits long. The first three bits represent status information indicating the sign and conversion state. The next 24 bits are the conversion result, MSB first. The remaining five bits are sub LSBs beyond the 24-bit level that may be included in averaging or discarded without loss of resolution. In the case of ultrahigh resolution modes, more than 24 effective bits of performance are possible (see Table 4). Under these conditions, sub LSBs are included in the conversion result and represent useful information beyond the 24-bit level. The third and fourth bit together are also used to indicate an underrange condition (the differential input voltage is below -FS) or an overrange condition (the differential input voltage is above +FS ).

Bit 31 (first output bit) is the end of conversion ( $\overline{\mathrm{EOC}}$ ) indicator. This bit is available at the SDO pin during the conversion and sleep states whenever the $\overline{\mathrm{CS}}$ pin is LOW. This bit is HIGH during the conversion and goes LOW when the conversion is complete.

Bit 30 (second output bit) is a dummy bit (DMY) and is always LOW.

Bit 29 (third output bit) is the conversion result sign indicator (SIG). If $\mathrm{V}_{\text {IN }}$ is $>0$, this bit is HIGH. If $\mathrm{V}_{\text {IN }}$ is $<0$, this bit is LOW.

Bit 28 (fourth output bit) is the most significant bit (MSB) of the result. This bit in conjunction with Bit 29 also provides the underrange or overrange indication. If both Bit 29 and Bit 28 are HIGH, the differential input voltage is above +FS . If both Bit 29 and Bit 28 are LOW, the differential input voltage is below -FS.
The function of these bits is summarized in Table 1.
Table 1. LTC2442 Status Bits

| Input Range | Bit 31 <br> $\overline{E O C}$ | Bit 30 <br> DMY | Bit 29 <br> SIG | Bit 28 <br> MSB |
| :--- | :---: | :---: | :---: | :---: |
| $V_{\text {IN }} \geq 0.5 \bullet V_{\text {REF }}$ | 0 | 0 | 1 | 1 |
| $0 \mathrm{~V} \leq V_{\text {IN }}<0.5 \bullet V_{\text {REF }}$ | 0 | 0 | 1 | 0 |
| $-0.5 \bullet V_{\text {REF }} \leq V_{\text {IN }}<0 \mathrm{~V}$ | 0 | 0 | 0 | 1 |
| $\mathrm{~V}_{\text {IN }}<-0.5 \bullet V_{\text {REF }}$ | 0 | 0 | 0 | 0 |

Bits 28-5 are the 24-bit conversion result MSB first.
Bit 5 is the least significant bit (LSB).
Bits 4-0 are sub LSBs below the 24-bit level. Bits 4-0 may be included in averaging or discarded without loss of resolution.

Data is shifted out of the SDO pin under control of the serial clock (SCK), see Figure 3. Whenever $\overline{\mathrm{CS}}$ is HIGH, SDO remains high impedance and SCK is ignored.
In order to shift the conversion result out of the device, $\overline{\mathrm{CS}}$ must first be driven LOW. $\overline{\mathrm{EOC}}$ is seen at the SDO pin of the device once $\overline{\mathrm{CS}}$ is pulled LOW. $\overline{\text { EOC }}$ changes real time from HIGH to LOW at the completion of a conversion. This signal may be used as an interrupt for an external microcontroller. Bit 31 ( $\overline{\mathrm{EOC}}$ ) can be captured on the first rising edge of SCK. Bit 30 is shifted out of the device on

## APPLICATIONS InFORMATION

the first falling edge of SCK. The final data bit (Bit 0) is shifted out on the falling edge of the 31st SCK and may be latched on the rising edge of the 32nd SCK pulse. On the falling edge of the 32nd SCK pulse, SDO goes HIGH indicating the initiation of a new conversion cycle. This bit serves as $\overline{\text { EOC }}$ (Bit 31) for the next conversion cycle. Table 2 summarizes the output data format.
As long as the voltage on the SEL ${ }^{+}$and SEL $^{-}$pins is maintained within the -0.3 V to $\left(\mathrm{V}_{\mathrm{CC}}+0.3 \mathrm{~V}\right)$ absolute maximum operating range, a conversion result is generated for any differential input voltage $\mathrm{V}_{\text {IN }}$ from $-F S=-0.5 \bullet \mathrm{~V}_{\text {REF }}$ to + FS $=0.5 \bullet V_{\text {REF }}$. For differential input voltages greater than +FS , the conversion result is clamped to the value corresponding to the $+\mathrm{FS}+1 \mathrm{LSB}$. For differential input voltages below -FS, the conversion result is clamped to the value corresponding to -FS - 1LSB.

## Serial Interface Pins

The LTC2442 transmits the conversion result and receives the start of conversion command through a synchronous 3- or 4-wire interface. During the conversion and sleep states, this interface can be used to access the converter status and during the data output state it is used to read the conversion result and program the speed, resolution and input channel.

## Serial Clock Input/Output (SCK)

The serial clock signal present on SCK (Pin 1) is used to synchronize the data transfer. Each bit of data is shifted out the SDO pin on the falling edge of the serial clock.

In the Internal SCK mode of operation, the SCK pin is an output and the LTC2442 creates its own serial clock. In the External SCK mode of operation, the SCK pin is used as input. The internal or external SCK mode is selected by tying EXT (Pin 3) LOW for external SCK and HIGH for internal SCK.

## Serial Data Output (SDO)

The serial data output pin, SDO (Pin 36), provides the result of the last conversion as a serial bit stream (MSB first) during the data output state. In addition, the SDO pin is used as an end of conversion indicator during the conversion and sleep states.
When $\overline{\mathrm{CS}}$ (Pin 35) is HIGH, the SDO driver is switched to a high impedance state. This allows sharing the serial interface with other devices. If $\overline{\mathrm{CS}}$ is LOW during the convert or sleep state, SDO will output $\overline{E O C}$. If $\overline{C S}$ is LOW during the conversion phase, the $\overline{\mathrm{EOC}}$ bit appears HIGH on the SDO pin. Once the conversion is complete, $\overline{\mathrm{EOC}}$ goes LOW. The device remains in the sleep state until the first rising edge of SCK occurs while $\overline{C S}=$ LOW.

## APPLICATIONS INFORMATION

Chip Select Input (도)

The active LOW chip select, $\overline{\mathrm{CS}}$ (Pin 35), is used to test the conversion status and to enable the data output transfer as described in the previous sections.

In addition, the $\overline{\mathrm{CS}}$ signal can be used to trigger a new conversion cycle before the entire serial data transfer has been completed. The LTC2442 will abort any serial data transfer in progress and start a new conversion cycle anytime a LOW-to-HIGH transition is detected at the $\overline{\mathrm{CS}}$ pin after the converter has entered the data output state.

## Serial Data Input (SDI)

The serial data input (SDI, Pin 33) is used to select the speed/resolution and input channel of the LTC2442. SDI is programmed by a serial input data stream under the control of SCK during the data output cycle, see Figure 3.
Initially, after powering up, the device performs a conversion with $\mathrm{SEL}^{+}=\mathrm{CHO}$, SEL ${ }^{-}=\mathrm{CH} 1, \mathrm{OSR}=256$ (output rate nominally 879 Hz ), and 1 X speedup mode (no latency). Once this first conversion is complete, the device enters the sleep state and is ready to output the conversion result and receive the serial data input stream programming the speed/resolution and input channel for the next conversion. At the conclusion of each conversion cycle, the device enters this state.

In order to change the speed/resolution or input channel, the first three bits shifted into the device are 101. This is compatible with the programming sequence of all LTC multichannel differential input $\Delta \Sigma$ ADCs. If the sequence is set to 000 or 100 , the following input data is ignored (don't care) and the previously selected speed/resolution and channel remain valid for the next conversion. Combinations other than 101, 100, and 000 of the three control bits should be avoided.

If the first three bits shifted into the device are 101, then the following five bits select the input channel for the following conversion (see Tables 3 and 4). The next five bits select the speed/resolution and mode 1X (no latency) 2X (double output rate with one conversion latency), see Table 4. If these five bits are set to all 0's, the previous speed remains selected for the next conversion. This is useful in applications requiring a fixed output rate/resolution but need to change the input channel.
When an update operation is initiated the first three bits are 101. The following five bits are the channel address. The first bit, SGL, determines if the input selection is differential ( $\mathrm{SGL}=0$ ) or single-ended $(\mathrm{SGL}=1)$. For SGL $=0$, two adjacent channels can be selected to form a differential input. For SGL = 1, one of 4 channels is selected as the positive input. The negative input is COM for all single ended operations. The next 4-bits (ODD, A2, A1, $\mathrm{A})$ ) determine which channel is selected and its polarity, (see Table 3). In order to remain software compatible with LTCs other multi-channel $\Delta \Sigma$ ADCs, A2 and A1 are unused and should be set low.

## Speed Multiplier Mode

In addition to selecting the speed/resolution, a speed multiplier mode is used to double the output rate while maintaining the selected resolution. The last bit of the 5-bit speed/resolution control word (TWOX, see Table 4) determines if the output rate is 1 X (no speed increase) or $2 X$ (double the selected speed).
While operating in the 1 X mode, the device combines two internal conversions for each conversion result in order to remove the ADC offset. Every conversion cycle, the offset and offset drift are transparently calibrated greatly simplifying the user interface. The resulting conversion result has no latency. The first conversion following a newly

## APPLICATIONS INFORMATION

selected speed/resolution and input channel is valid. This is identical to the operation of the LTC2440 and LTC2444 through LTC2449.

While operating in the 2 X mode, the device performs a running average of the last two conversion results. This automatically removes the offset and drift of the device while increasing the output rate by 2 X . The resolution (noise) remains the same. If a new channel is selected, the conversion result is valid for all conversions after the first conversion (one cycle latency). If a new speed/ resolution is selected, the first conversion result is valid but the resolution (noise) is a function of the running average. All subsequent conversion results are valid. If the mode is changed from either $1 X$ to $2 X$ or $2 X$ to $1 X$ without changing the resolution or channel, the first conversion result is valid.

The 2 X mode can also be used to increase the settling time of the amplifier between readings. While operating in the 2X mode, the multiplexer output (input to the buffer/ amplifier) is switched at the end of each conversion cycle. Prior to concluding the data out/in cycle, the analog multiplexer output is switched. This occurs at the end of the conversion cycle (just prior to the data output cycle) for auto calibration. The time required to read the conversion enables more settling time for the amplifier. The offset/ offset drift of the amplifier is automatically removed by the converter's auto calibration sequence for both the 1 X and 2 X speed modes.

While operating in the 1 X mode, if a new input channel is selected the multiplexer is switched on the falling edge of the 14th SCK (once the complete data input word is programmed). The remaining data output sequence time can be used to allow the external amplifier to settle.

## BUSY

The BUSY output (Pin 2) is used to monitor the state of conversion, data output and sleep cycle. While the part is converting, the BUSY pin is HIGH. Once the conversion is complete, BUSY goes LOW indicating the conversion is complete and data out is ready. The part now enters the sleep state. BUSY remains LOW while data is shifted out of the device and SDI is shifted into the device. It goes HIGH at the conclusion of the data input/output cycle indicating a new conversion has begun. This rising edge may be used to flag the completion of the data read cycle.

## Serial Interface Timing Modes

The LTC2442's 3- or 4-wire interface is SPI and MICROWIRE compatible. This interface offers several flexible modes of operation. These include internal/external serial clock, 3 - or 4 -wire I/ 0 , single cycle conversion and autostart. The following sections describe each of these serial interface timing modes in detail. In all these cases, the converter can use the internal oscillator ( $F_{0}=$ LOW) or an external oscillator connected to the $\mathrm{F}_{0}$ pin. Refer to Table 5 for a summary.

Table 5. Interface Timing Modes

| Configuration | SCK Source | Conversion Cycle Control | Data Output Control | Connection and Waveforms |
| :--- | :---: | :---: | :---: | :---: |
| External SCK, Single Cycle Conversion | External | $\overline{\text { CS }}$ and SCK | $\overline{\text { CS }}$ and SCK | Figures 4,5 |

| Internal SCK, 2-Wire I/O, Continuous <br> Conversion | Internal | Continuous | Internal | Figure 9 |

## APPLICATIONS INFORMATION

## External Serial Clock, Single Cycle Operation (SPI/MICROWIRE Compatible)

This timing mode uses an external serial clock to shift out the conversion result and a $\overline{\mathrm{CS}}$ signal to monitor and control the state of the conversion cycle, see Figure 4.

The serial clock mode is selected by the EXT pin. To select the external serial clock mode, EXT must be tied low.
The serial data output pin (SDO) is Hi-Z as long as $\overline{\mathrm{CS}}$ is HIGH. At any time during the conversion cycle, $\overline{\mathrm{CS}}$ may be pulled LOW in order to monitor the state of the converter. While $\overline{\mathrm{CS}}$ is pulled LOW, $\overline{\mathrm{EOC}}$ is output to the SDO pin. $\overline{E O C}=1$ (BUSY = 1) while a conversion is in progress and $\overline{E O C}=0(B U S Y=0)$ if the device is in the sleep state. Independent of $\overline{\mathrm{CS}}$, the device automatically enters the sleep state once the conversion is complete.

When the device is in the sleep state ( $\overline{\mathrm{EOC}}=0$ ), its conversion result is held in an internal static shift register. The device remains in the sleep state until the first rising edge of SCK is seen. Data is shifted out the SDO pin on each falling edge of SCK. This enables external circuitry to latch the output on the rising edge of SCK. $\overline{\mathrm{EOC}}$ can be latched on the first rising edge of SCK and the last bit of the conversion result can be latched on the 32nd rising edge of SCK. On the 32nd falling edge of SCK, the device begins a new conversion. SDO goes HIGH ( $\overline{\mathrm{EOC}}=1$ ) and BUSY goes HIGH indicating a conversion is in progress.
At the conclusion of the data cycle, $\overline{\mathrm{CS}}$ may remain LOW and $\overline{\mathrm{EOC}}$ monitored as an end-of-conversion interrupt. Alternatively, $\overline{\mathrm{CS}}$ may be driven HIGH setting SDO to $\mathrm{Hi}-\mathrm{Z}$ and BUSY monitored for the completion of a conversion.

Figure 4. External Serial Clock, Single Cycle Operation

## APPLICATIONS INFORMATION

As described above, $\overline{C S}$ may be pulled LOW at any time in order to monitor the conversion status on the SDO pin.
Typically, $\overline{\mathrm{CS}}$ remains LOW during the data output state. However, the data output state may be aborted by pulling $\overline{\mathrm{CS}}$ HIGH anytime between the fifth falling edge and the 32nd falling edge of SCK, see Figure 5. On the rising edge of $\overline{\mathrm{CS}}$, the device aborts the data output state and immediately initiates a new conversion. Thirteen serial input data bits are required in order to properly program the speed/ resolution and input channel. If the data output sequence
is aborted prior to the 13th rising edge of SCK, the new input data is ignored, and the previously selected speed/ resolution and channel are used for the next conversion cycle. This is useful for systems not requiring all 32 bits of output data, aborting an invalid conversion cycle or synchronizing the start of a conversion. If a new channel is being programmed, the rising edge of $\overline{\mathrm{CS}}$ must come after the 14th falling edge of SCK in order to store the data input sequence.

Figure 5. External Serial Clock, Reduced Output Data Length

## APPLICATIONS INFORMATION

## External Serial Clock, 2-Wire I/0

This timing mode utilizes a 2-wire serial I/O interface. The conversion result is shifted out of the device by an externally generated serial clock (SCK) signal, see Figure 6. $\overline{\mathrm{CS}}$ may be permanently tied to ground, simplifying the user interface or isolation barrier. The external serial clock mode is selected by tying EXT LOW.
Since $\overline{C S}$ is tied LOW, the end-of-conversion ( $\overline{\mathrm{EOC}}$ ) can be continuously monitored at the SDO pin during the convert and sleep states. Conversely, BUSY (Pin 2) may be used to monitor the status of the conversion cycle. $\overline{E O C}$ or BUSY may be used as an interrupt to an external
controller indicating the conversion result is ready. $\overline{\mathrm{EOC}}=$ 1 (BUSY = 1) while the conversion is in progress and EOC $=0(B U S Y=0)$ once the conversion enters the sleep state. On the falling edge of $\overline{E O C} / B U S Y$, the conversion result is loaded into an internal static shift register. The device remains in the sleep state until the first rising edge of SCK. Data is shifted out the SDO pin on each falling edge of SCK enabling external circuitry to latch data on the rising edge of SCK. EOC can be latched on the first rising edge of SCK. On the 32nd falling edge of SCK, SDO and BUSY go HIGH ( $\overline{\mathrm{EOC}}=1$ ) indicating a new conversion has begun.

Figure 6. External Serial Clock, $\overline{\text { CS }}=0$ Operation (2-Wire)

## APPLICATIONS INFORMATION

## Internal Serial Clock, Single Cycle Operation

This timing mode uses an internal serial clock to shift out the conversion result and a $\overline{\mathrm{CS}}$ signal to monitor and control the state of the conversion cycle, see Figure 7.

In order to select the internal serial clock timing mode, the EXT pin must be tied HIGH.
The serial data output pin (SDO) is Hi-Z as long as $\overline{\mathrm{CS}}$ is HIGH. At any time during the conversion cycle, $\overline{\mathrm{CS}}$ may be pulled LOW in order to monitor the state of the converter. Once $\overline{\mathrm{CS}}$ is pulled LOW, SCK goes LOW and $\overline{\mathrm{EOC}}$ is output to the SDO pin. EOC = 1 while a conversion is in progress and $\overline{E O C}=0$ if the device is in the sleep state. Alternatively, BUSY (Pin 2) may be used to monitor the status of the conversion in progress. BUSY is HIGH during the
conversion and goes LOW at the conclusion. It remains LOW until the result is read from the device.
When testing $\overline{\mathrm{EOC}}$, if the conversion is complete ( $\overline{\mathrm{EOC}}=$ 0 ), the device will exit the sleep state and enter the data output state if $\overline{\mathrm{CS}}$ remains LOW. In order to prevent the device from exiting the sleep state, $\overline{\mathrm{CS}}$ must be pulled HIGH before the first rising edge of SCK. In the internal SCK timing mode, SCK goes HIGH and the device begins outputting data at time $\mathrm{t}_{\text {EOCtest }}$ after the falling edge of $\overline{\mathrm{CS}}$ (if $\overline{\mathrm{EOC}}=0$ ) or $\mathrm{t}_{\text {EOCtest }}$ after $\overline{\mathrm{EOC}}$ goes LOW (if $\overline{\mathrm{CS}}$ is LOW during the falling edge of $\overline{\mathrm{EOC}}$ ). The value of $\mathrm{t}_{\text {EOCtest }}$ is 500 ns . If $\overline{\mathrm{CS}}$ is pulled HIGH before time $\mathrm{t}_{\text {EOCtest }}$, the device remains in the sleep state. The conversion result is held in the internal static shift register.

Figure 7. Internal Serial Clock, Single Cycle Operation

## APPLICATIONS InFORMATION

If $\overline{\mathrm{CS}}$ remains LOW Ionger than $\mathrm{t}_{\text {EOCtest }}$, the first rising edge of SCK will occur and the conversion result is serially shifted out of the SDO pin. The data output cycle begins on this first rising edge of SCK and concludes after the 32nd rising edge. Data is shifted out the SDO pin on each falling edge of SCK. The internally generated serial clock is output to the SCK pin. This signal may be used to shift the conversion result into external circuitry. EOC can be latched on the first rising edge of SCK and the last bit of the conversion result on the 32nd rising edge of SCK. After the 32nd rising edge, SDO goes HIGH ( $\overline{\mathrm{EOC}}=1$ ), SCK stays HIGH and a new conversion starts.

Typically, $\overline{\mathrm{CS}}$ remains LOW during the data output state. However, the data output state may be aborted by pulling
$\overline{\text { CS }}$ HIGH anytime between the first and 32nd rising edge of SCK, see Figure 8. On the rising edge of $\overline{\mathrm{CS}}$, the device aborts the data output state and immediately initiates a new conversion. This is useful for systems not requiring all 32 bits of output data, aborting an invalid conversion cycle, or synchronizing the start of a conversion. Thirteen serial input data bits are required in order to properly program the speed/resolution and input channel. If the data output sequence is aborted prior to the 13th rising edge of SCK, the new input data is ignored, and the previously selected speed/resolution and channel are used for the next conversion cycle. If a new channel is being programmed, the rising edge of $\overline{\mathrm{CS}}$ must come after the 14th falling edge of SCK in order to store the data input sequence.

Figure 8. Internal Serial Clock, Reduced Data Output Length

## APPLICATIONS INFORMATION

Internal Serial Clock, 3-Wire I/O, Continuous Conversion

This timing mode uses a 3-wire, all output (SCK and SDO) interface. The conversion result is shifted out of the device by an internally generated serial clock (SCK) signal, see Figure 9. $\overline{\mathrm{CS}}$ may be permanently tied to ground, simplifying the user interface or isolation barrier. The internal serial clock mode is selected by tying EXT HIGH.

During the conversion, the SCK and the serial data output pin (SDO) are HIGH ( $\overline{\mathrm{EOC}}=1$ ) and BUSY $=1$. Once the conversion is complete, SCK, BUSY and SDO go LOW $(\overline{\mathrm{EOC}}=0)$ indicating the conversion has finished and the
device has entered the sleep state. The part remains in the sleep state a minimum amount of time ( $\approx 500 \mathrm{~ns}$ ) then immediately begins outputting data. The data output cycle begins on the first rising edge of SCK and ends after the 32nd rising edge. Data is shifted out the SDO pin on each falling edge of SCK. The internally generated serial clock is output to the SCK pin. This signal may be used to shift the conversion result into external circuitry. $\overline{\mathrm{EOC}}$ can be latched on the first rising edge of SCK and the last bit of the conversion result can be latched on the 32nd rising edge of SCK. After the 32nd rising edge, SDO goes HIGH ( $\overline{\mathrm{EOC}}=1$ ) indicating a new conversion is in progress. SCK remains HIGH during the conversion.

Figure 9. Internal Serial Clock, Continuous Operation

## APPLICATIONS INFORMATION

## Normal Mode Rejection and Antialiasing

One of the advantages delta-sigma ADCs offer over conventional ADCs is on-chip digital filtering. Combined with a large oversampling ratio, the LTC2442 significantly simplifies antialiasing filter requirements.
The LTC2442's speed/resolution is determined by the oversample ratio (OSR) of the on-chip digital filter. The OSR ranges from 64 for 3.5 kHz output rate to 32,768 for 6.9 Hz (in No Latency mode) output rate. The value of OSR and the sample rate $\mathrm{f}_{\mathrm{S}}$ determine the filter characteristics of the device. The first NULL of the digital filter is at $f_{N}$ and multiples of $f_{N}$ where $f_{N}=f_{S} / O S R$, see Figure 10 and Table 6. The rejection at the frequency $\mathrm{f}_{\mathrm{N}} \pm 14 \%$ is better than 80dB, see Figure 11.

Figure 10. Normal Mode Rejection (Internal Oscillator)

| $32768^{*}$ | 55 Hz |

* Simultaneous 50/60Hz rejection

Figure 11. Normal Mode Rejection (Internal Oscillator)

## APPLICATIONS INFORMATION

If $F_{0}$ is grounded, $f_{S}$ is set by the on-chip oscillator at 1.8 MHz (over supply and temperature variations). At an OSR of 32,768 , the first NULL is at $f_{N}=55 \mathrm{~Hz}$ and the no latency output rate is $\mathrm{f}_{\mathrm{N}} / 8=6.9 \mathrm{~Hz}$. At the maximum OSR, the noise performance of the device is $220 \mathrm{nV} \mathrm{V}_{\mathrm{RMS}}$ with better than 80 dB rejection of $50 \mathrm{~Hz} \pm 2 \%$ and $60 \mathrm{~Hz} \pm 2 \%$. Since the OSR is large $(32,768)$ the wide band rejection is extremely large and the antialiasing requirements are simple. The first multiple of $\mathrm{f}_{\mathrm{S}}$ occurs at $55 \mathrm{~Hz} \cdot 32,768=$ 1.8MHz, see Figure 12.

The first NULL becomes $f_{N}=7.03 \mathrm{kHz}$ with an OSR of 256 (an output rate of 879 Hz ) and $\mathrm{F}_{0}$ grounded. While the NULL has shifted, the sample rate remains constant. As a result of constant modulator sampling rate, the linearity, offset and full-scale performance remains unchanged as does the first multiple of $\mathrm{f}_{\mathrm{s}}$.

The sample rate $f_{S}$ and NULL $f_{N}$, may also be adjusted by driving the $F_{0}$ pin with an external oscillator. The sample rate is $f_{S}=f_{\text {EOSC }} / 5$, where $f_{\text {EOSC }}$ is the frequency of the
clock applied to $\mathrm{F}_{0}$. Combining a large OSR with a reduced sample rate leads to notch frequencies $f_{N}$ near DC while maintaining simple antialiasing requirements. A 100 kHz clock applied to $\mathrm{F}_{0}$ results in a NULL at 0.6 Hz plus all harmonics up to 20 kHz , see Figure 13. This is useful in applications requiring digitalization of the DC component of a noisy input signal and eliminates the need of placing a 0.6 Hz filter in front of the ADC.

An external oscillator operating from 100 kHz to 12MHz can be implemented using the LTC1799 (resistor set SOT-23 oscillator), see Figure 14. By floating pin 4 (DIV) of the LTC1799, the output oscillator frequency is:

$$
\mathrm{f}_{\mathrm{OSC}}=10 \mathrm{MHz} \cdot\left(\frac{10 \mathrm{k}}{10 \cdot \mathrm{R}_{\mathrm{SET}}}\right)
$$

The normal mode rejection characteristic shown in Figure 13 is achieved by applying the output of the LTC1799 (with $\mathrm{R}_{\text {SET }}=100 \mathrm{k}$ ) to the $\mathrm{F}_{0}$ pin on the LTC2442 with OSR $=32,768$.

Figure 13. Normal Mode Rejection (Internal Oscillator at 90kHz)

## APPLICATIONS InFORMATION

## Input Bandwidth and Frequency Rejection

The combined effect of the internal SINC ${ }^{4}$ digital filter and the digital and analog autocalibration circuits determines the LTC2442 input bandwidth and rejection characteristics. The digital filter's response can be adjusted by setting the oversample ratio (OSR) through the SPI interface or by supplying an external conversion clock to the $\mathrm{F}_{0}$ pin.
Table 7 lists the properties of the LTC2442 with various combinations of oversample ratio and clock frequency. Understanding these properties is the key to fine tuning the characteristics of the LTC2442 to the application.

## Maximum Conversion Rate

The maximum conversion rate is the fastest possible rate at which conversions can be performed.

## First Notch Frequency

This is the first notch in the SINC ${ }^{4}$ portion of the digital filter and depends on the $f_{0}$ clock frequency and the oversample ratio. Rejection at this frequency and its multiples (up to the modulator sample rate of 1.8 MHz ) exceeds 120 dB . This is 8 times the maximum conversion rate.

## Effective Noise Bandwidth

The LTC2442 has extremely good inputnoise rejection from the first notch frequency all the way out to the modulator sample rate (typically 1.8 MHz ). Effective noise bandwidth is a measure of how the ADC will reject wideband input noise up to the modulator sample rate.

Table 7. Performance vs Oversample Ratio

| Oversample Ratio (OSR) | *RMS <br> Noise | ENOB <br> ( $\mathrm{V}_{\text {REF }}=$ 5 V ) | Maximum Conversion Rate (sps) |  |  | First Notch Frequency(Hz) |  | Effective Noise BW(Hz) |  | $\begin{aligned} & \hline \text {-3dB Point } \\ & \text { (Hz) } \end{aligned}$ |  |

*ADC noise increases by approximately $\sqrt{2}$ when OSR is decreased by a factor of 2 for OSR 32768 to OSR 256 . The ADC noise at OSR 64 include effects from internal modulator quantization noise.

Figure 14. Simple External Clock Source

## APPLICATIONS INFORMATION

## Optimizing Linearity

While the integrated op-amp has rail-to-rail input range, in order to achieve parts-per-million linearity performance, the input range and op-amp supply voltages must be considered. Input levels within 1.25 V of the upper op-amp rail $\left(\mathrm{V}^{+}\right)$begin to degrade the performance. For example (see Figure 15) while operating with $\mathrm{V}^{+}=5.1 \mathrm{~V}$ and absolute input voltages ( $\mathrm{V}_{\text {IN }} \mathrm{CM}+\mathrm{V}_{\text {IN }} \mathrm{DIFF}$ ) up to 3.75 V ( $\mathrm{V}_{\text {IN }} \mathrm{CM}=$ 2.5 V and $-2.5 \mathrm{~V}<\mathrm{V}_{\text {IN }} \mathrm{DIFF}<2.5 \mathrm{~V}$ ), the linearity is degraded to about 17 -bits. Once $\mathrm{V}^{+}$is increased to 5.25 V or greater

242 F15
Figure 15. INL vs Op-Amp Supply Voltage

2442 F17
Figure 17. Linearity Near Ground
the linearity improves to 19-Bits (2ppm). If the reference is reduced to 4.096 V and the input common mode is $\mathrm{V}_{\text {REF }} / 2$ (2.048V) the linearity performance improves to better than 1ppm with $\mathrm{V}^{+}$tied to $\mathrm{V}_{\mathrm{cc}}$ and $\mathrm{V}^{-}$tied to ground, see Figure 16. Input signals near ground require about 100 mV headroom on the op-amp power supply in order to achieve 1 ppm INL, see Figure 17. Optimal linearity is achieved by driving the input differentially. As seen in Figure 18, a single ended input (the negative input is tied to ground) yields 18-bits ( $\pm 4 \mathrm{ppm}$ ) linearity performance. In this case $\mathrm{V}^{-}$is 100 mV below ground.

Figure 16. Linearity vs $V_{\mathrm{IN}}$

2442 F18
Figure 18. Single-Ended Linearity

## APPLICATIONS INFORMATION

The LTC2442 breaks new ground in high impedance input $\Delta \Sigma$ ADCs. The input buffer is optimized to make driving the ADC as easy as possible, while overcoming many of the limitations typical of integrated buffers.

## Convenient +5 V to $-5 \mathrm{~V} /+9 \mathrm{~V}$ DC-DC Converter

If either of the signal inputs must include ground and $V_{C C}$, then the amplifier will require both a positive supply greater than the maximum input voltage and a negative supply. Figure 19 shows how to derive both -5 V and +9 V from a single 5V supply using an LTC1983, allowing the ADC inputs to extend as much as 300 mV below ground and above $\mathrm{V}_{\text {CC }}$. For inputs that include ground but do not go within 1.5 V of $\mathrm{V}_{\mathrm{C}}$, then $\mathrm{C} 4, \mathrm{C} 5, \mathrm{C} 6$ and D 1 can be eliminated and the amplifier positive supply can be connected to $\mathrm{V}_{\text {CC }}$.

## Input Bias Current

The $10 n A$ typical bias current of the buffers results in less than 1 ppm $(5 \mu \mathrm{~V})$ error for source resistance imbalances of less than $500 \Omega$. Matching the resistance at the inputs cancels much of the error due to amplifier bias current. For source resistances up to $50 \mathrm{k}, 1 \%$ resistors are adequate. Figure 20 shows proper input resistance matching for a precision voltage divider on the $\mathrm{CH} 2-3$ inputs. The resistance seen by CH 2 is the parallel combination of 30 k and 10 k or 7.5 k . A $1 \%, 7.5 \mathrm{k}$ resistor at CH 3 balances the resistance of the divider output.

While the two input buffers will have slightly different bias currents, the autozero process applies the biascurrent from each buffer to both of the inputs for half of the conversion time, so the offset is equal to the average of the two bias currents multiplied by the mismatch in source resistance.

Figure 19. LTC1983 with Another Charge Pump Stacked onto $\mathrm{V}_{\text {cc }}$ to Give 9V

## APPLICATIONS INFORMATION

Low Power Operation

The integrated buffers have a supply current of 1 mA total, greatly reducing the total power consumption when the ADC is operated at a low duty cycle. The typical approach to driving a $\Delta \Sigma$ ADC is to use a high bandwidth amplifier that settles very quickly in response to the sampling process at the ADC input. The LTC2442 approach is to use an accurate, low bandwidth amplifier that requires a load capacitor for compensation. This capacitor also serves as a charge reservoir during the sampling process, so the disturbance at the ADC input is minimal. The amplifier only supplies the average sampling current that the ADC draws, which is on the order of $50 \mu \mathrm{~A}$.

## Scaling for Higher Input Voltages

The LTC2442 is ideally suited for applications with low-level, differential signal with a common mode approximately equal to mid-supply, such as strain gages and silicon micromachined sensors. Other applications require scaling a high voltage signal to the range of the ADC.

Figure 20 shows how to properly scale a bipolar, ground-referred input voltage to drive the LTC2442. First, the input must be level shifted so that it never exceeds the LTC2442 supply rails. This is commonly done with an instrumenta-
tion amplifier or simple op-amp level shift circuit. Rather than shift the analog input, the LTC2442 can run on $\pm 2.5 \mathrm{~V}$ supplies so that ground is centered in the input range. This is equivalent to a perfect analog level shift with no degradation in accuracy. The digital signals are shifted from 0 V to 5 V logic to $\pm 2.5 \mathrm{~V}$ logic by a very inexpensive 74 HC 4053 analog switch and the data from the LTC2442 is shifted back to 0 to 5 V logic by a MMBT3904 transistor.

On both inputs, precision resistor networks scale the input signal from $\pm 10 \mathrm{~V}$ to $\pm 2.5 \mathrm{~V}$. CHO- 1 is driven truly differentially for maximum linearity, typically better than 3ppm, however 3 resistors and an LTC2050HV autozero amplifier are required. The $8.88 \mathrm{k} \Omega$ output resistor balances the offset associated with the LTC2442's bias current. The resistance seen by CHO is 4.44 k and the offset at CHO is also inverted and appears at the output of the LTC2050HV.

CH 2 to CH 3 is driven single-ended, with CH 3 tied to ground. This degrades linearity slightly, but it is easierto implement than a true differential drive. In this case the resistance at CH 3 should be equal to the resistance at CH 2 or 7.5 k . This circuit is also suitable for signals that are always positive, with the LTC2442 operating on a single 5V supply.

## LTC2442

## APPLICATIONS InFORMATION

Figure 20. Scaling Inputs for $\pm 10 \mathrm{~V}$ Range

## APPLICATIONS InFORMATION

## Details of the Conversion and Autozero Process

The LTC2442 performs automatic offset cancellation for each conversion. This is accomplished by taking the average of two "half-conversions" with the inputs applied in opposite polarity. Figure 21 shows a conversion on CHO to CH1 differential at OSR of 32768 , in $1 \times$ mode. This channel is selected by sending the appropriate configuration word to the LTC2442 through the SPI interface. On the $13^{\text {th }}$ falling clock edge, the CHO input is applied to +INA through the multiplexer and CH 1 is connected to +INB . The outputs of the amplifiers slew during the remainder of the data I/O state and the conversion begins on the $32^{\text {nd }}$ falling clock edge. Halfway through the conversion (approximately 73 ms later) the multiplexer switches the CHO input to +INB and the CH1 input to +INA. The digital filter subtracts the two half-conversions, which removes the offset of the amplifiers and converter.
At the end of a conversion, the multiplexer assumes that the next conversion will be on the same channel and switches back to the opposite polarity on the channel just converted. This gives extra settling time when converting on one channel continuously. If a different channel is programmed, the multiplexer will switch again on the $13^{\text {th }}$ falling clock edge.

The amplifiers take approximately $50 \mu \mathrm{~s}$ to settle for a full-scale input voltage. This does not affect accuracy in either $2 x$ mode or $1 \times$ mode for OSR values between 256 to 32768 . However, the amplifier settling time will cause a gain error in 1x mode for OSR values between 64 to 256. This is because the mid-conversion slew time is a

Figure 21. Amplifier Outputs and $\overline{\text { CS, }}$, SCK, BUSY During a Conversion on CHO-1, OSR32768. $\mathrm{V}_{\text {INDIFF }}=2.5 \mathrm{~V}, \mathrm{~V}_{\mathrm{CM}}=2.5 \mathrm{~V}$
significant portion of the total conversion time. Figure 22 shows the details of a conversion in 1x mode, OSR128, with a full-scale input voltage applied ( $\mathrm{V}_{\mathrm{IN}}=2.5 \mathrm{~V}, \mathrm{~V}_{\mathrm{CM}}=$ 2.5 V ). The previously selected channel had both inputs grounded. On the $13^{\text {th }}$ falling clock edge, the amplifiers begin slewing and have reached the correct voltage before the conversion begins. Midway throughthe conversion, the multiplexer reverses the inputs. Figure 23 shows operation in $2 x$ mode. After the first half-conversion is done, the multiplexer reverses. Waiting $50 \mu \mathrm{~s}$ before beginning the next half-conversion allows the amplifiers to settle fully. $2 x$ mode is recommended for OSR values between 64 and 128 because the amplifiers have time to settle between half conversions. If only the $1 x$ data rate is required, ignore every other sample.

| LT1025 | Micropower Thermocouple Cold Junction Compensator | 80رA Supply Current, $0.5^{\circ} \mathrm{C}$ Initial Accuracy |
| LTC1043 | Dual Precision Instrumentation Switched Capacitor Building Block | Precise Charge, Balanced Switching, Low Power |
| LTC2050 | Precision Chopper Stabilized Op Amp | No External Components $3 \mu \mathrm{~V}$ Offset, 1.5 5 V P-p Noise |
| LT1236A-5 | Precision Bandgap Reference, 5V | 0.05\% Max, 5ppm/ ${ }^{\circ} \mathrm{C}$ Drift |
| LT1461 | Micropower Series Reference, 2.5V | 0.04\% Max, 3ppm/ ${ }^{\circ} \mathrm{C}$ Max Drift |
| LT1592 | Ultraprecise 16-Bit SoftSpan ${ }^{\text {TM }}$ DAC | Six Programmable Output Ranges |
| LTC1799 | Resistor Set SOT-23 Oscillator | Single Resistor Frequency Set |
| LTC1983 | 100mA Charge Pump | 5V to Regulated -5V Conversion |
| LTC2053 | Rail-to-Rail Instrumentation Amplifier | $10 \mu \mathrm{~V}$ Offset with $50 \mathrm{nV} /{ }^{\circ} \mathrm{C}$ Drift, $2.5 \mu \mathrm{~V}_{\text {P-p }}$ Noise 0.01 Hz to 10 Hz |
| LTC2440 | 1-Channel, Differential Input, High Speed/Low Noise, 24-Bit, No Latency $\Delta \Sigma$ ADC | $2 \mu \mathrm{~V}_{\text {RMS }}$ Noise at $880 \mathrm{~Hz}, 200 \mathrm{nV}$ RMS Noise at 6.9 Hz , $0.0005 \%$ INL, Up to 3.5 kHz Output Rate |
