## 16-Bit, 105Msps Low Noise ADC

## feATURES

- Sample Rate: 105Msps
- 81.3dBFS Noise Floor
- 100dB SFDR
- SFDR >90dB at 70 MHz
- $85 \mathrm{fs}_{\text {RMS }}$ Jitter
- 2.75V P-p Input Range
- 400MHz Full Power Bandwidth S/H
- Optional Internal Dither
- Optional Data Output Randomizer
- LVDS or CMOS Outputs
- Single 3.3V Supply
- Power Dissipation: 1.19W
- Clock Duty Cycle Stabilizer
- Pin Compatible with LTC2208
- 64-Pin ( $9 \mathrm{~mm} \times 9 \mathrm{~mm}$ ) QFN Package

## APPLICATIONS

- Telecommunications
- Receivers
- Cellular Base Stations
- Spectrum Analysis
- Imaging Systems
- ATE

## DESCRIPTIOn

The LTC ${ }^{\circledR} 2217$ is a 105 Msps sampling 16 -bit A/D converter designed for digitizing high frequency, wide dynamic range signals with input frequencies up to 400 MHz . The input range of the ADC is fixed at 2.75 V p-p.
The LTC2217 is perfect for demanding communications applications, with AC performance that includes 81.3dBFS Noise Floor and 100dB spurious free dynamic range (SFDR). Ultra low jitter of 85fsRms allows undersampling of high input frequencies while maintaining excellent noise performance. Maximum DC specifications include $\pm 3.5 \mathrm{LSB}$ INL, $\pm 1$ LSB DNL (no missing codes).
The digital output can be either differential LVDS or single-ended CMOS. There are two format options for the CMOS outputs: a single bus running at the full data rate or demultiplexed buses running at half data rate. A separate output power supply allows the CMOS output swing to range from 0.5 V to 3.6 V .
The ENC ${ }^{+}$and ENC- inputs may be driven differentially or single-ended with a sine wave, PECL, LVDS, TTL or CMOS inputs. An optional clock duty cycle stabilizer allows high performance at full speed with a wide range of clock duty cycles.

## TYPICAL APPLICATION

64k Point FFT, $\mathrm{F}_{\mathrm{IN}}=4.9 \mathrm{MHz},-1 \mathrm{dBFS}$

ABSOLUTE MAXIMUM RATIOGS$0 V_{D D}=V_{D D}$ (Notes 1 and 2)
Supply Voltage (VD)

$\qquad$
-0.3 V to 4 V
Digital Output Ground Voltage (OGND)........-0.3V to 1 V Analog Input Voltage (Note 3) ..... -0.3 V to (VDD +0.3 V )
Digital Input Voltage -0.3 V to $\left(\mathrm{V}_{\mathrm{DD}}+0.3 \mathrm{~V}\right)$
Digital Output Voltage................ -0.3 V to ( $0 \mathrm{~V}_{\mathrm{DD}}+0.3 \mathrm{~V}$ )
Power Dissipation. $\qquad$ 2000 mW

## Operating Temperature Range

 LTC2217C . $0^{\circ} \mathrm{C}$ to $70^{\circ} \mathrm{C}$ LTC22171 $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$Storage Temperature Range

$\qquad$
$-65^{\circ} \mathrm{C}$ to $150^{\circ} \mathrm{C}$ Digital Output Supply Voltage ( OV DD ).......... -0.3 V to 4 V

## ELECTRICAL CHARACTERISTICS

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.
Note 2: All voltage values are with respect to GND, with GND and OGND shorted (unless otherwise noted).
Note 3: When these pin voltages are taken below $G N D$ or above $V_{D D}$, they will be clamped by internal diodes. This product can handle input currents of greater than 100 mA below $G N D$ or above $V_{D D}$ without latchup.
Note 4: $V_{D D}=3.3 \mathrm{~V}, \mathrm{f}_{\text {SAMPLE }}=105 \mathrm{MHz}$, LVDS outputs, differential ENC ${ }^{+} /$ $E N C^{-}=2 V_{\text {P-p }}$ sine wave with 1.6 V common mode, input range $=2.75 \mathrm{~V}_{\mathrm{P}-\mathrm{P}}$ with differential drive, unless otherwise specified.

Note 5: Integral nonlinearity is defined as the deviation of a code from a "best fit straight line" to the transfer curve. The deviation is measured from the center of the quantization band.
Note 6: Offset error is the offset voltage measured from $-1 / 2$ LSB when the output code flickers between 0000000000000000 and 111111111111 1111 in 2's complement output mode.
Note 7: Guaranteed by design, not subject to test.
Note 8: Recommended operating conditions.

## TYPICAL PERFORMANCE CHARACTERISTICS

## PIN fUnCTIOnS

For CMOS Mode. Full Rate or Demultiplexed

SENSE (Pin 1): Reference Mode Select and External Reference Input. Tie SENSE to $V_{D D}$ to select the internal 2.5 V bandgap reference. An external reference of 2.5 V or 1.25 V may be used; both reference values will set a full scale ADC range of 2.75 V .
GND (Pins 2, 4, 7, 10, 11, 14, 18): ADC Power Ground.
$\mathrm{V}_{\text {CM }}$ (Pin3): 1.575 V Output. Optimum voltage for inputcommon mode. Must be bypassed to ground with a minimum of $2.2 \mu \mathrm{~F}$. Ceramic chip capacitors are recommended.
$V_{D D}$ (Pins 5, 6, 15, 16, 17): 3.3V Analog Supply Pin. Bypass to GND with $1 \mu \mathrm{~F}$ ceramic chip capacitors.
$\mathrm{A}_{\mathrm{IN}}{ }^{+}$(Pin 8): Positive Differential Analog Input.
$A_{\text {IN }}{ }^{-}$(Pin 9): Negative Differential Analog Input.
ENC ${ }^{+}$(Pin 12): Positive Differential Encode Input. The sampled analog input is held on the rising edge of ENC+. Internally biased to 1.6 V through a $6.2 \mathrm{k} \Omega$ resistor. Output data can be latched on the rising edge of ENC ${ }^{+}$.
ENC- (Pin 13): Negative Differential Encode Input. The sampled analog input is held on the falling edge of ENC ${ }^{-}$. Internally biased to 1.6 V through a $6.2 \mathrm{k} \Omega$ resistor. Bypass to ground with a $0.1 \mu \mathrm{~F}$ capacitor for a single-ended Encode signal.
SHDN (Pin 19): Power Shutdown Pin. SHDN = low results in normal operation. SHDN = high results in powered down analog circuitry and the digital outputs are placed in a high impedance state.
DITH (Pin 20): Internal Dither Enable Pin. DITH = Iow disables internal dither. DITH = high enables internal dither. Refer to Internal Dither section of this data sheet for details on dither operation.
DB0-DB15 (Pins 21-30 and 33-38): Digital Outputs, BBus. DB15 is the MSB. Active in demultiplexed mode. The B bus is in high impedance state in full rate CMOS mode.

OGND (Pins 31 and 50): Output Driver Ground.
OV ${ }_{\text {DD }}$ (Pins 32 and 49): Positive Supply for the Output Drivers. Bypass to ground with $1 \mu \mathrm{~F}$ capacitor.
OFB (Pin 39): Over/Under Flow Digital Output for the B Bus. OFB is high when an over or under flow has occurred on the $B$ bus. At high impedance state in full rate CMOS mode.

CLKOUTB (Pin 40): Data Valid Output. CLKOUTB willtoggle at the sample rate in full rate CMOS mode or at $1 / 2$ the sample rate in demultiplexed mode. Latch the data on the falling edge of CLKOUTB.

CLKOUTA (Pin 41): Inverted Data Valid Output. CLKOUTA will toggle at the sample rate in full rate CMOS mode or at $1 / 2$ the sample rate in demultiplexed mode. Latch the data on the rising edge of CLKOUTA.
DAO-DA15 (Pins 42-48 and51-59): Digital Outputs, A Bus. DA15 is the MSB. Output bus for full rate CMOS mode and demultiplexed mode.
OFA (Pin 60): Over/Under Flow Digital Output for the A Bus. OFA is high when an over or under flow has occurred on the $A$ bus.
LVDS (Pin 61): Data Output Mode Select Pin. Connecting LVDS to OV selects full rate CMOS mode. Connecting LVDS to $1 / 3 \mathrm{~V}_{\mathrm{DD}}$ selects demultiplexed CMOS mode. Connecting LVDS to 2/3V ${ }_{\text {DD }}$ selects Low Power LVDS mode. Connecting LVDS to $V_{D D}$ selects Standard LVDS mode.
MODE (Pin 62): Output Format and Clock Duty Cycle Stabilizer Selection Pin. Connecting MODE to OV selects offset binary output format and disables the clock duty cycle stabilizer. Connecting MODE to $1 / 3 \mathrm{~V}_{\text {DD }}$ selects offset binary output format and enables the clock duty cycle stabilizer. Connecting MODEto $2 / 3 V_{D D}$ selects 2's complement output format and enables the clock duty cycle stabilizer. Connecting MODE to $V_{D D}$ selects 2's complement output format and disables the clock duty cycle stabilizer.
RAND (Pin 63): Digital Output Randomization Selection Pin. RAND low results in normal operation. RAND high selects D1-D15 to be EXCLUSIVE-ORed with D0 (the LSB). The output can be decoded by again applying an XOR operation between the LSB and all other bits. This mode of operation reduces the effects of digital output interference.

NC (Pin 64): NotConnected Internally. For pin compatibility with the LTC2208 this pin should be connected to GND or $V_{D D}$ as required. Otherwise no connection.
GND (Exposed Pad): ADC Power Ground. The exposed pad on the bottom of the package must be soldered to ground.

## PIn functions

## For LVDS Mode. STANDARD or LOW POWER

SENSE (Pin 1): Reference Mode Select and External Reference Input. Tie SENSE to $V_{D D}$ to select the internal 2.5 V bandgap reference. An external reference of 2.5 V or 1.25 V may be used; both reference values will set a full scale ADC range of 2.75 V .
GND (Pins 2, 4, 7, 10, 11, 14, 18): ADC Power Ground.
$V_{\text {CM }}$ (Pin 3): 1.575V Output. Optimum voltage for input common mode. Must be bypassed to ground with a minimum of $2.2 \mu$ F. Ceramic chip capacitors are recommended.
$V_{D D}$ (Pins 5, 6, 15, 16, 17): 3.3V Analog Supply Pin. Bypass to GND with $1 \mu \mathrm{~F}$ ceramic chip capacitors.
$\mathrm{A}_{\mathrm{IN}^{+}}$(Pin 8): Positive Differential Analog Input.
$A_{I N}{ }^{-}$(Pin 9): Negative Differential Analog Input.
ENC ${ }^{+}$(Pin 12): Positive Differential Encode Input. The sampled analog input is held on the rising edge of ENC ${ }^{+}$. Internally biased to 1.6 V through a $6.2 \mathrm{k} \Omega$ resistor. Output data can be latched on the rising edge of ENC ${ }^{+}$.
ENC${ }^{-}$(Pin 13): Negative Differential Encode Input. The sampled analog input is held on the falling edge of ENC ${ }^{-}$. Internally biased to 1.6 V through a $6.2 \mathrm{k} \Omega$ resistor. Bypass to ground with a $0.1 \mu \mathrm{~F}$ capacitor for a single-ended Encode signal.
SHDN (Pin 19): Power Shutdown Pin. SHDN = low results in normal operation. SHDN = high results in powered down analog circuitry and the digital outputs are set in high impedance state.
DITH (Pin 20): Internal Dither Enable Pin. DITH = low disables internal dither. DITH = high enables internal dither. Refer to Internal Dither section of the data sheet for details on dither operation.
$\mathrm{DO}^{-/} / \mathrm{DO}^{+}$to $\mathrm{D} 15-/ \mathrm{D}^{-} 5^{+}$(Pins 21-30, 33-38, 41-48 and 51-58): LVDS Digital Outputs. All LVDS outputs require differential $100 \Omega$ termination resistors at the LVDS receiver. D15 ${ }^{+} /$D15 $^{-}$is the MSB.

OGND (Pins 31 and 50): Output Driver Ground.
$0 V_{D D}$ (Pins 32 and 49): Positive Supply for the Output Drivers. Bypass to ground with $0.1 \mu \mathrm{~F}$ capacitor.
CLKOUT-/CLKOUT+ (Pins 39 and 40): LVDS Data Valid Output. Latch data on the rising edge of CLKOUT ${ }^{+}$, falling edge of CLKOUT ${ }^{-}$.
OF-/OF+(Pins 59 and 60 ): Over/Under Flow Digital Output OF is high when an over or under flow has occurred.
LVDS (Pin 61): Data Output Mode Select Pin. Connecting LVDS to OV selects full rate CMOS mode. Connecting LVDS to $1 / 3 \mathrm{~V}_{\text {DD }}$ selects demultiplexed CMOS mode. Connecting LVDS to $2 / 3 V_{D D}$ selects Low Power LVDS mode. Connecting LVDS to $V_{D D}$ selects Standard LVDS mode.
MODE (Pin 62): Output Format and Clock Duty Cycle Stabilizer Selection Pin. Connecting MODE to OV selects offset binary output format and disables the clock duty cycle stabilizer. Connecting MODE to $1 / 3 V_{D D}$ selects offset binary output format and enables the clock duty cycle stabilizer. Connecting MODE to $2 / 3 V_{D D}$ selects 2's complement output format and enables the clock duty cycle stabilizer. Connecting MODE to $\mathrm{V}_{\mathrm{DD}}$ selects 2's complement output format and disables the clock duty cycle stabilizer.
RAND (Pin63): Digital OutputRandomization Selection Pin. RAND low results in normal operation. RAND high selects D1-D15 to be EXCLUSIVE-ORed with D0 (the LSB). The output can be decoded by again applying an XOR operation between the LSB and all other bits. The mode of operation reduces the effects of digital output interference.
NC (Pin 64): Not Connected Internally. For pin compatibility with the LTC2208 this pin should be connected to GND or $V_{D D}$ as required. Otherwise no connection.
GND (Exposed Pad Pin 65): ADC Power Ground. The exposed pad on the bottom of the package must be soldered to ground.

## bLOCK DIAGRAM

Figure 1. Functional Block Diagram

## OPERATION

## DYNAMIC PERFORMANCE

## Signal-to-Noise Plus Distortion Ratio

The signal-to-noise plus distortion ratio $[\mathrm{S} /(\mathrm{N}+\mathrm{D})]$ is the ratio between the RMS amplitude of the fundamental input frequency and the RMS amplitude of all other frequency components at the ADC output. The output is band limited to frequencies above DC to below half the sampling frequency (Nyquist Frequency).

## Signal-to-Noise Ratio

The signal-to-noise (SNR) is the ratio between the RMS amplitude of the fundamental inputfrequency and the RMS amplitude of all other frequency components, except the first five harmonics.

## Total Harmonic Distortion

Total harmonic distortion is the ratio of the RMS sum of all harmonics of the input signal to the fundamental itself. The out-of-band harmonics alias into the frequency band between DC and half the sampling frequency (Nyquist Frequency). THD is expressed as:

$$
T H D=-20 L o g\left(\frac{\sqrt{\left(V_{2}^{2}+V_{3}^{2}+V_{4}^{2}+\ldots V_{N}^{2}\right)}}{V_{1}}\right)
$$

where $\mathrm{V}_{1}$ is the RMS amplitude of the fundamental frequency and $\mathrm{V}_{2}$ through $\mathrm{V}_{\mathrm{N}}$ are the amplitudes of the second through nth harmonics.

## Intermodulation Distortion

If the ADC input signal consists of more than one spectral component, the ADC transfer function nonlinearity can produce intermodulation distortion (IMD) in addition to THD. IMD is the change in one sinusoidal input caused
by the presence of another sinusoidal input at a different frequency.
If two pure sine waves of frequencies fa and fb are applied to the ADC input, nonlinearities in the ADC transferfunction can create distortion products at the sum and difference frequencies of $\mathrm{mfa} \pm \mathrm{nfb}$, where m and $\mathrm{n}=0,1,2,3$, etc. For example, the 3rd order IMD terms include ( $2 \mathrm{fa}+\mathrm{fb}$ ), (fa $+2 \mathrm{fb})$ ), (2fa - fb) and (fa - 2fb). The 3rd order IMD is defined as the ratio of the RMS value of either input tone to the RMS value of the largest 3rd order IMD product.

## Spurious Free Dynamic Range (SFDR)

The ratio of the RMS input signal amplitude to the RMS value of the peak spurious spectral component expressed in dBc. SFDR may also be calculated relative to full scale and expressed in dBFS.

## Full Power Bandwidth

The Full Power bandwidth is that input frequency at which the amplitude of the reconstructed fundamental is reduced by 3 dB from a full scale input signal.

## Aperture Delay Time

The time from when a rising ENC ${ }^{+}$equals the ENC $^{-}$voltage to the instant that the input signal is held by the sample-and-hold circuit.

## Aperture Delay Jitter

The variation in the aperture delay time from conversion to conversion. This random variation will result in noise when sampling an AC input. The signal-to-noise ratio term due to the jitter alone will be:

$$
\text { SNR }_{\text {JITTER }}=-20 \log \left(2 \pi \bullet f_{I N} \bullet \mathrm{t}_{\text {JTTER }}\right)
$$

This formula states SNR due to jitter aloneat any amplitude in terms of dBc.

## APPLICATIONS INFORMATION

## CONVERTER OPERATION

The LTC2217 is aCMOS pipelined multistep converter with a low noise front-end. As shown in Figure 1, the converter has five pipelined ADC stages; a sampled analog input will result in a digitized value seven cycles later (see the Timing Diagram section). The analog input is differential for improved common mode noise immunity and to maximize the input range. Additionally, the differential input drive will reduce even order harmonics of the sample and hold circuit. The encode input is also differential for improved common mode noise immunity.
The LTC2217 has two phases of operation, determined by the state of the differential ENC+/ENC- input pins. For brevity, the text will refer to ENC ${ }^{+}$greater than ENC ${ }^{-}$as ENC high and ENC ${ }^{+}$less than ENC ${ }^{-}$as ENC low.
Each pipelined stage shown in Figure 1 contains an ADC, a reconstruction DAC and an interstage amplifier. In operation, the ADC quantizes the input to the stage and the quantized value is subtracted from the input by the DAC to produce a residue. The residue is amplified and output by the residue amplifier. Successive stages operate out of phase so that when odd stages are outputting their residue, the even stages are acquiring that residue and vice versa.

When ENC is low, the analog input is sampled differentially directly onto the input sample-and-hold capacitors, inside the "input S/H" shown in the block diagram. At the instant that ENC transitions from low to high, the voltage on the sample capacitors is held. While ENC is high, the held input voltage is buffered by the S/H amplifier which drives the first pipelined ADC stage. The firststage acquires the output of the S/H amplifier during the high phase of ENC. When ENC goes back low, the first stage produces its residue which is acquired by the second stage. At the same time, the input $\mathrm{S} / \mathrm{H}$ goes back to acquiring the analog input. When ENC goes high, the second stage produces its residue which is acquired by the third stage. An identical process is repeated for the third and fourth stages, resulting in a fourth stage residue that is sent to the fifth stage for final evaluation.
Each ADC stage following the first has additional range to accommodate flash and amplifier offset errors. Results from all of the ADC stages are digitally delayed such that the results can be properly combined in the correction logic before being sent to the output buffer.

## SAMPLE/HOLD OPERATION AND INPUT DRIVE

## Sample/Hold Operation

Figure 2 shows an equivalent circuit for the LTC2217 CMOS differential sample and hold. The differential analog inputs are sampled directly onto sampling capacitors (CSAMPLE) through NMOS transitors. The capacitors shown attached to each input (CPARASITIC) are the summation of all other capacitance associated with each input.
During the sample phase when ENC is low, the NMOS transistors connect the analog inputs to the sampling capacitors and they charge to, and track the differential input voltage. When ENC transitions from low to high, the sampled input voltage is held on the sampling capacitors. During the hold phase when ENC is high, the sampling capacitors are disconnected from the input and the held voltage is passed to the ADC core for processing. As ENC transitions for high to low, the inputs are reconnected to the sampling capacitors to acquire a new sample. Since the sampling capacitors still hold the previous sample, a charging glitch proportional to the change in voltage between samples will be seen at this time. If the change between the last sample and the new sample is small, the charging glitch seen at the input will be small. If the

Figure 2. Equivalent Input Circuit

## APPLICATIONS InFORMATION

input change is large, such as the change seen with input frequencies near Nyquist, then a larger charging glitch will be seen.

## Common Mode Bias

The ADC sample-and-hold circuit requires differential drive to achieve specified performance. Each input should swing $\pm 0.6875 \mathrm{~V}$ for the 2.75 V range, around a common mode voltage of 1.575 V . The $\mathrm{V}_{\text {CM }}$ output pin (Pin 3 ) is designed to provide the common mode bias level. $\mathrm{V}_{\text {CM }}$ can be tied directly to the center tap of a transformer to set the DC input level or as a reference level to an op amp differential driver circuit. The $\mathrm{V}_{\mathrm{CM}}$ pin must be bypassed to ground close to the ADC with $2.2 \mu \mathrm{~F}$ or greater.

## Input Drive Impedance

As with all high performance, high speed ADCs the dynamic performance of the LTC2217 can be influenced by the input drive circuitry, particularly the second and third harmonics. Source impedance and input reactance can influence SFDR. At the falling edge of ENC the sample and hold circuit will connect the sampling capacitor to the input pin and start the sampling period. The sampling period ends when ENC rises, holding the sampled input on the sampling capacitor. Ideally, the inputcircuitry should be fast enough to fully charge the sampling capacitor during the sampling period $1 /\left(2 \bullet f_{\text {ENCODE }}\right)$; however, this is not always possible and the incomplete settling may degrade the SFDR. The sampling glitch has been designed to be as linear as possible to minimize the effects of incomplete settling.

For the best performance it is recommended to have a source impedance of $100 \Omega$ or less for each input. The source impedance should be matched for the differential inputs. Poor matching will result in higher even order harmonics, especially the second.

## INPUT DRIVE CIRCUITS

## Input Filtering

A first-order RC low-pass filter at the input of the ADC can serve two functions: limit the noise from input circuitry and provide isolation from ADC S/H switching. The LTC2217
has a very broadband S/H circuit, DC to 400MHz; it can be used in a wide range of applications; therefore, it is not possible to provide a single recommended RC filter.

Figures 3 and 4 show two examples of input RC filtering for two ranges of input frequencies. In general it is desirable to make the capacitors as large as can be tolerated-this will help suppress random noise as well as noise coupled from the digital circuitry. The LTC2217 does not require any input filter to achieve data sheet specifications; however, no filtering will put more stringent noise requirements on the input drive circuitry.

## Transformer Coupled Circuits

Figure 3 shows the LTC2217 being driven by an RF transformer with a center-tapped secondary. The secondary center tap is DC biased with $\mathrm{V}_{\mathrm{CM}}$, setting the ADC input signal at its optimum DC level. Figure 3 shows a 1:1 turns ratio transformer. Other turns ratios can be used; however, as the turns ratio increases so does the impedance seen by the ADC. Source impedance greater than $50 \Omega$ can reduce the input bandwidth and increase high frequency distortion. A disadvantage of using a transformer is the loss of low frequency response. Mostsmall RFtransformers have poor performance at frequencies below 1 MHz .

Center-tapped transformers provide a convenient means of DC biasing the secondary; however, they often show poor balance at high input frequencies, resulting in large 2nd order harmonics.

Figure 3. Single-Ended to Differential Conversion Using a Transformer. Recommended for Input Frequencies from 5 MHz to 100 MHz

## APPLICATIONS InFORMATION

Figure 4 shows transformer coupling using a transmission line balun transformer. This type of transformer has much better high-frequency response and balance than flux coupled center-tap transformers. Coupling capacitors are added at the ground and input primary terminals to allow the secondary terminals to be biased at 1.575 V .

Figure 4. Using a Transmission Line Balun Transformer.
Recommended for Input Frequencies from 100 MHz to 250 MHz

## Direct Coupled Circuits

Figure 5 demonstrates the use of a differential amplifier to convert a single ended input signal into a differential input signal. The advantage of this method is that it provides low frequency input response; however, the limited gain bandwidth of any op amp or closed-loop amplifier will degrade the ADC SFDR athigh inputfrequencies. Additionally, wideband op amps or differential amplifiers tend to have high noise. As a result, the SNR will be degraded unless the noise bandwidth is limited prior to the ADC input.

## Reference Operation

Figure 6 shows the LTC2217 reference circuitry consisting of a 2.5 V bandgap reference, a programmable gain amplifier and control circuit. The LTC2217 has three modes of reference operation: Internal Reference, 1.25V external reference or 2.5 V external reference. To use the internal

Figure 5. DC Coupled Input with Differential Amplifier
reference, tie the SENSE pin to $V_{D D}$. To use an external reference, simply apply either a 1.25 V or 2.5 V reference voltage to the SENSE input pin. Both 1.25 V and 2.5 V applied to SENSE will result in a full scale range of $2.75 \mathrm{~V}_{\text {P-p. }} \mathrm{A}$ 1.575 V output, $\mathrm{V}_{\mathrm{CM}}$, is provided for a common mode bias for input drive circuitry. An external bypass capacitor is required for the $\mathrm{V}_{\text {CM }}$ output. This provides ahigh frequency low impedance path to ground for internal and external circuitry. This is also the compensation capacitor for the reference; which will not be stable without this capacitor. The minimum value required for stability is $2.2 \mu \mathrm{~F}$.

Figure 6. Reference Circuit

## APPLICATIONS InFORMATION

The internal programmable gain amplifier provides the internal reference voltage for the ADC. This amplifier has very stringent settling requirements and therefore is not accessible for external use.

The SENSE pin can be driven $\pm 5 \%$ around the nominal 2.5 V or 1.25 V external reference inputs. This adjustment range can be used to trim the ADC gain error or other system gain errors. When selecting the internal reference, the SENSE pin should be tied to $V_{D D}$ as close to the converter as possible. If the sense pin is driven externally it should be bypassed to ground as close to the device as possible with $1 \mu \mathrm{~F}$ ceramic capacitor.

Figure 7. A 2.75V Range ADC with an External 2.5V Reference

## Driving the Encode Inputs

The noise performance of the LTC2217 can depend on the encode signal quality as much as on the analog input. The encode inputs are intended to be driven differentially, primarily for noise immunity from common mode noise sources. Each input is biased through a 6 k resistor to a 1.6 V bias. The bias resistors set the DC operating point for transformer coupled drive circuits and can set the logic threshold for single-ended drive circuits.

Any noise present on the encode signal will result in additional aperture jitter that will be RMS summed with the inherent ADC aperture jitter.
In applications where jitter is critical (high input frequencies), take the following into consideration:

1. Differential drive should be used.
2. Use as large an amplitude possible. If using transformer coupling, use a higher turns ratio to increase the amplitude.
3. If the ADC is clocked with a fixed-frequency sinusoidal signal, filter the encode signal to reduce wideband noise.
4. Balance the capacitance and series resistance at both encode inputs such that any coupled noise will appear at both inputs as common mode noise.
The encode inputs have a common mode range of 1.2 V to $V_{D D}$. Each input may be driven from ground to $V_{D D}$ for single-ended drive.

# APPLICATIONS InFORMATION 

Figure 9. Single-Ended ENC Drive, Not Recommended for Low Jitter

Figure 10. ENC Drive Using a CMOS to PECL Translator

## Maximum and Minimum Encode Rates

The maximum encode rate for the LTC2217 is 105Msps. For the ADC to operate properly the encode signal should have a $50 \%$ ( $\pm 5 \%$ ) duty cycle. Each half cycle must have at least $4.5 n$ for the ADC internal circuitry to have enough settling time for proper operation. Achieving a precise 50\% duty cycle is easy with differential sinusoidal drive using a transformer or using symmetric differential logic such as PECL or LVDS. When using a single-ended ENCODE signal asymmetric rise and fall times can result in duty cycles that are far from $50 \%$.

An optional clock duty cycle stabilizer can be used if the input clock does not have a $50 \%$ duty cycle. This circuit uses the rising edge of ENC pin to sample the analog input. The falling edge of ENC is ignored and an internal falling edge is generated by a phase-locked loop. The input clock duty cycle can vary from $30 \%$ to $70 \%$ and the clock duty cycle stabilizer will maintain a constant $50 \%$ internal duty cycle. If the clock is turned off for a long period of time, the duty cycle stabilizer circuit will require one hundred clock cycles for the PLL to lock onto the input clock. To use the clock duty cycle stabilizer, the MODE pin must be connected to $1 / 3 \mathrm{~V}_{D D}$ or $2 / 3 \mathrm{~V}_{\mathrm{DD}}$ using external resistors.

The lower limit of the LTC2217 sample rate is determined by droop affecting the sample and hold circuits. The pipelined architecture of this ADC relies on storing analog signals on small valued capacitors. Junction leakage will discharge the capacitors. The specified minimum operating frequency for the LTC2217 is 1 Msps .

## DIGITAL OUTPUTS

## Digital Output Modes

The LTC2217 can operate in four digital output modes: standard LVDS, low power LVDS, full rate CMOS, and demultiplexed CMOS. The LVDS pin selects the mode of operation. This pin has a four level logic input, centered at $0,1 / 3 V_{D D}, 2 / 3 V_{D D}$ and $V_{D D}$. An external resistor divider can be used to set the $1 / 3 \mathrm{~V}_{D D}$ and $2 / 3 \mathrm{~V}_{D D}$ logic levels. Table 1 shows the logic states for the LVDS pin.

Table 1. LVDS Pin Function

| LVDS | DIGITAL OUTPUT MODE |
| :--- | :--- |
| $O V(G N D)$ | Full-Rate CMOS |
| $1 / 3 V_{D D}$ | Demultiplexed CMOS |
| $2 / 3 V_{D D}$ | Low Power LVDS |
| $V_{D D}$ | LVDS |

## Digital Output Buffers (CMOS Modes)

Figure 11 shows an equivalent circuit for a single output buffer in CMOS Mode, Full-Rate or Demultiplexed. Each buffer is powered by $0 V_{D D}$ and OGND, isolated from the ADC power and ground. The additional N-channel transistor in the output driverallows operation down to low voltages. The internal resistor in series with the output makes the output appear as $50 \Omega$ to external circuitry and eliminates the need for external damping resistors.
As with all high speed/high resolution converters, the digital output loading can affect the performance. The digital outputs of the LTC2217 should drive a minimum capacitive load to avoid possible interaction between the digital outputs and sensitive input circuitry. The output should be buffered with a device such as a ALVCH16373 CMOS latch. For full speed operation the capacitive load should be kept under 10pF. A resistor in series with the

## APPLICATIONS INFORMATION

output may be used, but is not required since the ADC has a series resistor of $43 \Omega$ on-chip.

Lower $\mathrm{O}_{\mathrm{DD}}$ voltages will also help reduce interference from the digital outputs.

Figure 11. Equivalent Circuit for a Digital Output Buffer

## Digital Output Buffers (LVDS Modes)

Figure 12 shows an equivalent circuit for an LVDS output pair. A 3.5 mA current is steered from OUT ${ }^{+}$to OUT $^{-}$or vice versa, which creates a $\pm 350 \mathrm{mV}$ differential voltage across the $100 \Omega$ termination resistor at the LVDS receiver. A feedback loop regulates the common mode output voltage to 1.20 V . For proper operation each LVDS output pair must be terminated with an external $100 \Omega$ termination
resistor, even if the signal is not used (such as $\mathrm{OF}^{+} / \mathrm{OF}^{-}$or CLKOUT ${ }^{+}$/CLKOUT ${ }^{-}$). To minimize noise the PC board traces for each LVDS output pair should be routed close together. To minimize clock skew all LVDS PC board traces should have about the same length.
In Low Power LVDS Mode 1.75 mA is steered between the differential outputs, resulting in $\pm 175 \mathrm{mV}$ at the LVDS receiver's $100 \Omega$ termination resistor. The output common mode voltage is 1.20 V , the same as standard LVDS Mode.

## Data Format

The LTC2217 parallel digital output can be selected for offset binary or 2's complement format. The format is selected with the MODE pin. This pin has a four level logic input, centered at $0,1 / 3 V_{D D}, 2 / 3 V_{D D}$ and $V_{D D}$. An external resistor divider can be user to set the $1 / 3 \mathrm{~V}_{\mathrm{DD}}$ and $2 / 3 \mathrm{~V}_{\mathrm{DD}}$ logic levels. Table 2 shows the logic states for the MODE pin.

Table 2. MODE Pin Function

| MODE | OUTPUT FORMAT | CLOCK DUTY <br> CYCLE STABILIZER |
| :---: | :---: | :---: |
| $0(G N D)$ | Offset Binary | Off |
| $1 / 3 V_{D D}$ | Offset Binary | On |
| $2 / 3 V_{D D}$ | 2's Complement | On |
| $V_{D D}$ | 2's Complement | Off |

Figure 12. Equivalent Output Buffer in LVDS Mode

## APPLICATIONS INFORMATION

Overflow Bit
An overflow output bit (OF) indicates when the converter is over-ranged or under-ranged. In CMOS mode, a logic high on the OFA pin indicates an overflow or underflow on the A data bus, while a logic high on the OFB pin indicates an overflow on the B data bus. In LVDS mode, a differential logic high on $\mathrm{OF}^{+} / \mathrm{OF}^{-}$pins indicates an overflow or underflow.

## Output Clock

The ADC has a delayed version of the encode input available as a digital output, CLKOUT. The CLKOUT pin can be used to synchronize the converter data to the digital system. This is necessary when using a sinusoidal encode. In both CMOS modes, A bus data will be updated as CLKOUTA falls and CLKOUTB rises. In demultiplexed CMOS mode the B bus data will be updated as CLKOUTA falls and CLKOUTB rises.
In Full Rate CMOS Mode, only the A data bus is active; data may be latched on the rising edge of CLKOUTA or the falling edge of CLKOUTB.
In demultiplexed CMOS mode CLKOUTA and CLKOUTB will toggle at $1 / 2$ the frequency of the encode signal. Both the A bus and the B bus may be latched on the rising edge of CLKOUTA or the falling edge of CLKOUTB.

## Digital Output Randomizer

Interference from the ADC digital outputs is sometimes unavoidable. Interference from the digital outputs may be from capacitive or inductive coupling, or coupling through the ground plane. Even a tiny coupling factor can result in discernible unwanted tones in the ADC output spectrum. By randomizing the digital output before it is transmitted off chip, these unwanted tones can be randomized, trading a slight increase in the noise floor for a large reduction in unwanted tone amplitude.
The digital output is "Randomized" by applying an exclu-sive-OR logic operation between the LSB and all other data output bits. To decode, the reverse operation is applied; that is, an exclusive-OR operation is applied between the

LSB and all other bits. The LSB, OF and CLKOUT output are not affected. The output Randomizer function is active when the RAND pin is high.

Figure 13. Functional Equivalent of Digital Output Randomizer

## Output Driver Power

Separate output power and ground pins allow the output drivers to be isolated from the analog circuitry. The power supply for the digital output buffers, $0 \mathrm{~V}_{\mathrm{DD}}$, should be tied to the same power supply as for the logic being driven. For example, if the converter is driving a DSP powered by a 1.8 V supply, then $\mathrm{OV}_{\mathrm{DD}}$ should be tied to that same 1.8 V supply. In CMOS mode $\mathrm{OV}_{\mathrm{DD}}$ can be powered with any logic voltage up to the 3.6 V . OGND can be powered with any voltage from ground up to 1 V and must be less than $\mathrm{OV}_{\mathrm{DD}}$. The logic outputs will swing between OGND and $\mathrm{OV}_{D D}$. In LVDS Mode, $\mathrm{OV}_{D D}$ should be connected to a 3.3 V supply and OGND should be connected to GND.

## APPLICATIONS INFORMATION

## Internal Dither

The LTC2217 is a 16-bit ADC with a very linear transfer function; however, at low input levels even slight imperfections in the transfer function will result in unwanted tones. Small errors in the transfer function are usually a result of ADC element mismatches. An optional internal dither mode can be enabled to randomize the input location on the ADC transfer curve, resulting in improved SFDR for low signal levels.
As shown in Figure 15, the output of the sample-and-hold amplifier is summed with the output of a dither DAC. The dither DAC is driven by a long sequence pseudo-random number generator; the random numberfed to the ditherDAC is also subtracted from the ADC result. If the dither DAC is precisely calibrated to the ADC, very little of the dither signal will be seen at the output. The dither signal that does leak through will appear as white noise. The dither DAC is calibrated to result in typically less than 0.5 dB elevation in the noise floor of the ADC as compared to the noise floor with dither off, when a suitable input termination is provided (see Demo Board schematic DC996B).

## LTC2217

## APPLICATIONS INFORMATION

## Grounding and Bypassing

The LTC2217 requires a printed circuit board with a clean unbroken ground plane; a multilayer board with an internal ground plane is recommended. The pinout of the LTC2217 has been optimized for a flowthrough layout so that the interaction between inputs and digital outputs is minimized. Layout for the printed circuit board should ensure that digital and analog signal lines are separated as much as possible. In particular, care should be taken not to run any digital track alongside an analog signal track or underneath the ADC.

High quality ceramic bypass capacitors should be used at the $V_{D D}, V_{C M}$, and $O V_{D D}$ pins. Bypass capacitors must be located as close to the pins as possible. The traces
connecting the pins and bypass capacitors must be kept short and should be made as wide as possible.
The LTC2217 differential inputs should run parallel and close to each other. The input traces should be as short as possible to minimize capacitance and to minimize noise pickup.

## Heat Transfer

Most of the heat generated by the LTC2217 is transferred from the die through the bottom-side exposed pad. For good electrical and thermal performance, the exposed pad must be soldered to a large grounded pad on the PC board. It is critical that the exposed pad and all ground pins are connected to a ground plane of sufficient area with as many vias as possible.
