## 160 MSPS Dual Continuous Time Sigma-Delta ADC

## FEATURES

SNR: $\mathbf{8 3} \mathbf{~ d B ~ ( ~} \mathbf{8 5} \mathbf{d B F S}$ ) to $\mathbf{1 0 ~ M H z}$ input
SFDR: -87 dBc to 10 MHz input
Noise figure: 15 dB
Input impedance: 1 k $\Omega$
Power: 600 mW
1.8 V analog supply operation
1.8 V to 3.3 V output supply

Selectable bandwidth
2.5 MHz/5 MHz/10 MHz real
$5 \mathrm{MHz} / 10 \mathrm{MHz} / 20 \mathrm{MHz}$ complex
Output data rate: $\mathbf{3 0}$ MSPS to 160 MSPS
Integrated dc and quadrature correction
Integrated decimation filters
Integrated sample rate converter
On-chip PLL clock multiplier
On-chip voltage reference
Offset binary, Gray code, or twos complement data format
Serial control interface (SPI)

## APPLICATIONS

Baseband quadrature receivers: CDMA2000, W-CDMA, multicarrier GSM/EDGE, 802.16x and LTE

## Quadrature sampling instrumentation

Medical equipment
Radio detection and ranging (RADAR)

## GENERAL DESCRIPTION

The AD9262 is a dual channel, 16-bit analog-to-digital converter (ADC) based on a continuous time (CT) sigma-delta ( $\Sigma-\Delta$ ) architecture that achieves -87 dBc of dynamic range over a 10 MHz input bandwidth. The integrated features and characteristics unique to the continuous time $\Sigma-\Delta$ architecture significantly simplify its use and minimize the need for external components.

The AD9262 has a resistive input impedance that relaxes the requirements of the driver amplifier. In addition, a $32 \times$ oversampled fifth-order continuous time loop filter significantly attenuates out-of-band signals and aliases, reducing the need for external filters at the input.
An external clock input or the integrated integer-N PLL provides the 640 MHz internal clock needed for the oversampled continuous time $\Sigma-\Delta$ modulator. On-chip decimation filters and sample rate converters reduce the modulator data rate from 640 MSPS to a user-defined output data rate between 30 MSPS and 160 MSPS, enabling a more efficient and direct interface.

The AD9262 incorporates an integrated dc correction and quadrature estimation block that corrects for gain and phase mismatch between the two channels. This functional block proves invaluable in complex signal processing applications such as direct conversion receivers.

The digital output data is presented in offset binary, Gray code, or twos complement format. A data clock output (DCO) is provided to ensure proper timing with the receiving logic. The AD9262 has the added feature of interleaving Channel A and Channel B data onto one 16-bit bus, simplifying on-board routing.
The ADC is available in three different bandwidth options of $2.5 \mathrm{MHz}, 5 \mathrm{MHz}$, and 10 MHz , and operates on a 1.8 V analog supply and a 1.8 V to 3.3 V digital supply, consuming 600 mW . The AD9262 is available in a 64 -lead LFCSP and is specified over the industrial temperature range $\left(-40^{\circ} \mathrm{C}\right.$ to $\left.+85^{\circ} \mathrm{C}\right)$.

## PRODUCT HIGHLIGHTS

1. Continuous time $\Sigma-\Delta$ architecture efficiently achieves high dynamic range and wide bandwidth.
2. Passive input structure reduces or eliminates the requirements for a driver amplifier.
3. An oversampling ratio of $32 \times$ and high order loop filter provide excellent alias rejection reducing or eliminating the need for antialiasing filters.
4. An integrated decimation filter, sample rate converter, PLL clock multiplier, and voltage reference provide ease of use.
5. Integrated dc correction and quadrature error correction.
6. Operates from a single 1.8 V analog power supply and 1.8 V to 3.3 V output supply.

${ }^{1}$ See the AN-83 5 Application Note, Understanding High Speed ADC Testing and Evaluation, for a complete set of definitions.
${ }^{2}$ Data skew is measured from DCO 50\% transition to data (D0x to D15x) 50\% transition, with 5 pF load.
${ }^{3}$ Typical measured value for the AD9262BCPZ-10. For the AD9262BCPZ-5 and the AD9262BCPZ, typical values double and quadruple the number of cycles, respectively.
${ }^{4}$ Cycles refers to modulator clock cycles.
${ }^{5}$ Wake-up time is dependent on the value of the decoupling capacitor, value shown with 10 uF capacitor on VREF and CFILT.
${ }^{6}$ See Figure 60 and the Serial Port Interface (SPI) section.

| VIN+A/VIN-A, VIN+B/VIN -B to AGND | -0.3 V to +2.0 V |
| CLK+, CLK- to CGND |  |
| Environmental | $-65^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| Operating Temperature Range | $300^{\circ} \mathrm{C}$ |
| Lead Temperature (Soldering, 10 Sec$)$ |  |
| Junction Temperature | $150^{\circ} \mathrm{C}$ |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## THERMAL RESISTANCE

The exposed paddle must be soldered to the ground plane for the LFCSP package. Soldering the exposed paddle to the PCB increases the reliability of the solder joints, maximizing the thermal capability of the package.

Table 7. Thermal Resistance

| Package Type | $\boldsymbol{\theta}_{\mathrm{JA}}$ | $\boldsymbol{\theta}_{\mathrm{Jc}}$ | Unit |
| :--- | :--- | :--- | :--- |
| 64-Lead LFCSP (CP-64-4) | 21.2 | 1.1 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

Typical $\theta_{J A}$ and $\theta_{J C}$ are specified for a 4-layer board in still air. Airflow increases heat dissipation, effectively reducing $\theta_{\mathrm{JA}}$. In addition, metal in direct contact with the package leads from metal traces, through holes, ground, and power planes reduces the $\theta_{\mathrm{IA}}$.

## ESD CAUTION

|  | ESD (electrostatic discharge) sensitive device. <br> Charged devices and circuit boards can discharge <br> without detection. Although this product features <br> patented or proprietary protection circuitry, damage <br> may occur on devices subjected to high energy ESD. <br> Therefore, proper ESD precautions should be taken to <br> avoid performance degradation or loss of functionality. |
| :--- | :--- |

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

NOTES

1. THE EXPOSED PAD MUST BE SOLDERED TO THE GROUND PLANE FOR THE LFCSP PACKAGE. SOLDERING THE EXPOSED PADDLE TO THE PCB INCREASES THE RELIABILITY OF THE SOLDER JOINTS, MAXIMIZING THE THERMAL CAPACITY OF THE PACKAGE.

Figure 3. Pin Configuration
Table 8. Pin Function Descriptions

| Pin No. | Mnemonic | Description |
| :---: | :---: | :---: |
| 1 | CLK- | Clock Input (-). |
| 2 | CVDD | Clock Supply (1.8 V). |
| 3 to 5, 9 to 21 | D0B to D15B | Channel B Data Output Pins. DOB is the LSB and D15B is the MSB. |
| 6, 25, 43 | DVDD | Digital Supply (1.8V). |
| 7, 24, 42 | DGND | Digital Ground. |
| 8, 23,41 | DRVDD | Digital Output Driver Supply ( 1.8 V to 3.3 V ). |
| 22 | ORB | Channel B Overrange Indicator. |
| 26 | DCO | Data Clock Output. |
| 27 to 40, 44, 45 | D0A to D15A | Channel A Data Output Pins. D0A is the LSB and D15A is the MSB. |
| 46 | ORA | Channel A Overrange Indicator. |
| 47 | SDIO | Serial Port Interface Data Input/Output. |
| 48 | SCLK | Serial Port Interface Clock. |
| 49 | CSB | Serial Port Interface Chip Select Active Low. |
| 50 | RESET | Chip Reset. |
| 51,62 | AGND | Analog Ground. |
| 52, 55, 58, 61 | AVDD | Analog Supply (1.8V). |
| 53 | VIN+A | Channel A Analog Input (+). |
| 54 | VIN-A | Channel A Analog Input (-). |
| 56 | VREF | Voltage Reference Input. |
| 57 | CFILT | Noise Limiting Filter Capacitor. |
| 59 | VIN+B | Channel B Analog Input (+). |
| 60 | VIN-B | Channel B Analog Input (-). |
| 63 | CGND | Clock Ground. |
| 64 | CLK+ | Clock Input (+). |
| 65 (EPAD) | Exposed pad (EPAD) | Analog Ground. (Pin 65 is the exposed thermal pad on the bottom of the package.) The exposed pad must be soldered to ground. |

## AD9262

## TYPICAL PERFORMANCE CHARACTERISTICS

All power supplies set to $1.8 \mathrm{~V}, 640 \mathrm{MHz}$ sample rate, 2 V p-p differential input, 0.5 V internal reference, PLL disabled, $\mathrm{AIN}=-2.0 \mathrm{dBFS}$, $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, output data rate 40 MSPS , unless otherwise noted.

## AD9262

## THEORY OF OPERATION

The AD9262 uses a continuous time $\Sigma-\Delta$ modulator to convert the analog input to a digital word. The digital word is processed by the decimation filter and rate-adjusted by the sample rate converter (see Figure 37). The modulator consists of a continuous time loop filter preceding a quantizer that samples at $\mathrm{f}_{\text {MOD }}=$ 640 MSPS. This produces an oversampling ratio (OSR) of 32 for a 10 MHz input bandwidth. The output of the quantizer is fed back to a DAC that ideally cancels the input signal. The incomplete input cancellation residue is filtered by the loop filter and is used to form the next quantizer sample.

Figure 37. $\Sigma$ - $\Delta$ Modulator Overview
The quantizer produces a nine-level digital word. The quantization noise is spread uniformly over the Nyquist band (see Figure 38), but the feedback loop causes the quantization noise present in the nine-level output to have a nonuniform spectral shape. This noise-shaping technique (see Figure 39) pushes the in-band noise out of band; therefore, the amount of quantization noise in the frequency band of interest is minimal.
The digital decimation filter that follows the modulator removes the large out-of-band quantization noise (see Figure 40), while also reducing the data rate from $\mathrm{f}_{\text {MOD }}$ to $\mathrm{f}_{\mathrm{MOD}} / 16$. If the internal PLL is enabled, the sample rate converter generates samples at the same frequency as the input clock frequency. If the internal PLL is disabled, the sample rate converter can be programmed to give an output frequency that is a divide ratio of the modulator clock. The sample rate converter is designed to attenuate images outside the band of interest (see Figure 41).

Figure 39. Noise Shaping

Figure 40. Digital Filter Cutoff Frequency

Figure 41. Sample Rate Converter

## ANALOG INPUT CONSIDERATIONS

The continuous time modulator removes the need for an antialias filter at the input to the AD9262. A discrete time converter aliases signals around the sample clock frequency and its multiples to the band of interest (see Figure 42). Therefore, an external antialias filter is needed to reject these signals.

Figure 42. Discrete Time Converter
In contrast, the continuous time $\Sigma-\Delta$ modulator used within the AD9262 has inherent antialiasing. The antialiasing property results from sampling occurring at the output of the loop filter (see Figure 43), and thus aliasing occurs at the same point in the loop as quantization noise is injected; aliases are shaped by the same mechanism as quantization noise. The quantization noise transfer function, $\operatorname{NTF}(\mathrm{f})$, has zeros in the band of interest and in all alias bands because $\operatorname{NTF}(\mathrm{f})$ is a discrete time transfer function, whereas the loop filter transfer function, $\operatorname{LF}(\mathrm{f})$, is a continuous time transfer function, which introduces poles only in the band of interest. The signal transfer function, being the product of $\operatorname{NTF}(\mathrm{f})$ and $\operatorname{LF}(\mathrm{f})$, only has zeros in alias bands and therefore suppresses all aliases.

Figure 43. Continuous Time Converter

## Input Common Mode

The analog inputs of the AD9262 are not internally dc biased. In ac-coupled applications, the user must provide this bias externally. Setting the device such that $\mathrm{V}_{\mathrm{CM}}=$ AVDD is recommended for optimum performance. The analog inputs are $500 \Omega$ resistors, and the internal reference loop aims to develop 0.5 V across each input resistor (see Figure 44). With 0 V differential input, the driver sources 1 mA into each analog input.

Figure 44. Input Common Mode

## Differential Input Configurations

The AD9262 can also be configured for differential inputs. The ADA4937-2 differential driver provides excellent performance and a flexible interface to the ADC. The output common-mode voltage of the ADA4937-2 is easily set by connecting AVDD to the Voсм2 pin of the ADA4937-2 (see Figure 45). The noise and linearity of the ADA4937-2 need important consideration because the system performance may be limited by the ADA4937-2.

Figure 45. Differential Input Configuration Using the ADA4937-2
For frequencies offset from dc, where SNR is a key parameter, differential transformer coupling is the recommended input configuration. An example is shown in Figure 46. The center tap of the secondary winding of the transformer is connected to AVDD to bias the analog input.
The signal characteristics must be considered when selecting a transformer. Most RF transformers saturate at frequencies below a couple of megahertz ( MHz ), and excessive signal power can cause core saturation, which leads to distortion.

Figure 46. Differential Transformer Configuration

## Voltage Reference

A stable and accurate 0.5 V voltage reference is built into the AD9262. The reference voltage should be decoupled to minimize the noise bandwidth using a $10 \mu \mathrm{~F}$ capacitor. The reference is used to generate a bias current into a matched resistor such that, when used to bias the current in the feedback DAC, a voltage of AVDD -0.5 V is developed at the internal side of the input resistors (see Figure 47). The current bias circuit should also be decoupled on the CFILT pin with a $10 \mu \mathrm{~F}$ capacitor. For this reason, the VREF voltage should always be 0.5 V .

Figure 47. Voltage Reference Loop

## Internal Reference Connection

To minimize thermal noise, the internal reference on the AD9262 is an unbuffered 0.5 V . It has an internal $10 \mathrm{k} \Omega$ series resistor, which, when externally decoupled with a $10 \mu \mathrm{~F}$ capacitor, limits the noise (see Figure 48). The unbuffered reference should not be used to drive any external circuitry. The internal reference is used by default and when Serial Register 0x18[6] is reset.

Figure 48. Internal Reference Configuration

## External Reference Operation

If an external reference is desired, the internal reference can be disabled by setting Serial Register 0x18[6] high. Figure 49 shows an application using the ADR130B as a stable external reference.

Figure 49. External Reference Configuration

## CLOCK INPUT CONSIDERATIONS

The AD9262 offers two modes of sourcing the ADC sample clock (CLK+ and CLK-). The first mode uses an on-chip clock multiplier that accepts a reference clock operating at the lower input frequency. The on-chip phase-locked loop (PLL) then multiplies the reference clock to a higher frequency, which is then used to generate all the internal clocks required by the ADC

The clock multiplier provides a high quality clock that meets the performance requirements of most applications. Using the on-chip clock multiplier removes the burden of generating and distributing the high speed clock.
The second mode bypasses the clock multiplier circuitry and allows the clock to be directly sourced. This mode enables the user to source a very high quality clock directly to the $\Sigma-\Delta$ modulator. Sourcing the ADC clock directly may be necessary in demanding applications that require the lowest possible ADC output noise. See Figure 28, which shows the degradation in SNR performance for the various PLL settings.
In either case, when using the on-chip clock multiplier or sourcing the high speed clock directly, it is necessary that the clock source have low jitter to maximize the ADC noise performance. High speed, high resolution ADCs are sensitive to the quality of the clock input. As jitter increases, the SNR performance of the AD9262 degrades from that specified in Table 2. The jitter inherent in the part due to the PLL root sum squares with any external clock jitter, thereby degrading performance. To prevent jitter from dominating the performance of the AD9262, the input clock source should be no greater than 1 ps rms of jitter.
The CLK $\pm$ inputs are self-biased to 450 mV (see Figure 31); if the inputs are dc-coupled, it is important to maintain the specified 450 mV input common-mode voltage. Each input pin can safely swing from 200 mV p-p to 1 V p-p single-ended about the 450 mV common-mode voltage. The recommended clock inputs are CMOS or LVPECL.

The specified clock rate of the $\Sigma-\Delta$ modulator, $\mathrm{f}_{\text {MOD }}$, is 640 MHz . The clock rate possesses a direct relationship to the available input bandwidth of the ADC.

$$
\text { Bandwidth }=f_{M O D} \div 64
$$

In either case, using the on-chip clock multiplier to generate the $\Sigma-\Delta$ modulator clock rate or directly sourcing the clock, any deviation from 640 MHz results in a change in input band-
width. The input range of the clock is limited to $640 \mathrm{MHz} \pm 5 \%$. In situations where the AD9262 loses its clock and then later regains it, it is important that the sample rate converter be reset and reprogrammed before the desired output data rate is achieved.

## Direct Clocking

The default configuration of the AD9262 is for direct clocking where the PLL is bypassed. Figure 50 shows one preferred method for clocking the AD9262. A low jitter clock source is converted from a single-ended signal to a differential signal using an RF transformer. The back-to-back Schottky diodes across the secondary side of the transformer limits clock excursions into the AD9262 to approximately 0.8 V p-p differential. This helps prevent the large voltage swings of the clock from feeding through to other portions of the AD9262 while preserving the fast rise and fall times of the signal, which are critical to achieving low jitter.

Figure 50. Transformer-Coupled Differential Clock
If a differential clock is not available, the AD9262 can be driven by a single-ended signal into the CLK+ terminal with the CLKterminal ac-coupled to ground. Figure 51 shows the circuit configuration.

Figure 51. Single-Ended Clock
Another option is to ac couple a differential LVPECL signal to the sample clock input pins, as shown in Figure 52. The AD951x family of clock drivers is recommended because it offers excellent jitter performance.

${ }^{1} 50 \Omega$ RESISTORS ARE OPTIONAL.

Figure 52. Differential LVPECL Sample Clock

## Internal PLL Clock Distribution

The alternative clocking option available on the AD9262 is to apply a low frequency reference clock and use the on-chip clock multiplier to generate the high frequency f f MOD rate. The internal clock architecture is shown in Figure 53.

Figure 53. Internal Clock Architecture
The clock multiplication circuit operates such that the VCO outputs a frequency, fvco, equal to the reference clock input multiplied by N .

$$
\mathrm{f}_{V C O}=(C L K \pm) \times(N)
$$

where N is the PLL multiplication (PLLMULT) factor.
The $\Sigma-\Delta$ modulator clock frequency, $\mathrm{f}_{\mathrm{MOD}}$, is equal to

$$
f_{M O D}=f_{V C O} \div 2
$$

The reference clock, CLK $\pm$, is limited to 30 MHz to 160 MHz when configured to use the on-chip clock multiplier. Given the input range of the reference clock and the available multiplication factors, the fyco is approximately 1280 MHz . This results in the desired $\mathrm{f}_{\text {MOD }}$ rate of 640 MHz with a $50 \%$ duty cycle.
Before the PLL enable register bit (PLLENABLE) is set, the PLL multiplication factor should be programmed into Register $0 x 0 \mathrm{~A}[5: 0]$. After setting the PLLENABLE bit, the PLL locks and reports a locked state in Register 0x0A[7]. If the PLL multiplication factor is changed, the PLL enable bit should be reset and set again. Some common clock multiplication factors are shown in Table 11.
The recommended sequence for enabling and programming the on-chip clock multiplier is shown in Table 9.

Table 9. Sequence for Enabling and Programming the PLL

| Step | Procedure |
| :--- | :--- |
| 1 | Apply a reference clock to the CLK $\pm$ pins. |
| 2 | Program the PLL multiplication factor in |
|  | Register 0x0A[5:0]. See Table 10. |
| 3 | Enable the PLL; Register 0x09 $=04$ (decimal). |
| 4 | Enable PLL autoband select. |
| 5 | Initiate an SRC reset; Register 0x101[5:0] $=0$. |
| 6 | Set SRC to desired value via Register 0x101[5:0]. |

## PLL Autoband Select

The PLL VCO has a wide operating range that is covered by overlapping frequency bands. For any desired VCO output frequency, there are multiple valid PLL band select values. The AD9262 possesses an automatic PLL band select feature on chip that determines the optimal PLL band setting. This feature can be enabled by writing to Register 0x0A[6] and is the recommended configuration with the PLL clocking option. When the device is taken out of sleep or standby mode, Register 0x0A[6] must be toggled to reinitiate the autoband detect. See Table 9 for information about enabling the autoband select along with configuring the PLL.

Table 10. PLL Multiplication Factors

## Jitter Considerations

The aperture jitter requirements for continuous time $\Sigma-\Delta$ converters may be more forgiving than Nyquist rate converters. The continuous time $\Sigma-\Delta$ architecture is an oversampled system and to accurately represent the analog input signal to the ADC, a large number of output samples must be averaged together. As a result, the jitter contribution from each sample is root sum squared, resulting in a more subtle impact on noise performance as compared to Nyquist converters where aperture jitter has a direct impact on each sampled output.
In the block diagram of the continuous time $\Sigma$ - $\Delta$ modulator (see Figure 37), the two building blocks most susceptible to jitter are the quantizer and the DAC. The error introduced through the sampling process is reduced by the loop gain and shaped in the same way as the quantization noise and, therefore, its effect can be neglected. On the contrary, the jitter error associated with the DAC directly adds to the input signal, thus increasing the in-band noise power and degrading the modulator performance. The SNR degradation due to jitter can be represented by the following equation.

$$
S N R=-20 \log \left(2 \pi f_{\text {analog }} t_{i j t t e r} \text { _rms }\right) \mathrm{dB}
$$

where $f_{\text {analog }}$ is the analog input frequency and $t_{j i t t e r}$ rms $i$ is the jitter.
The SNR performance of the AD9262 remains constant within the input bandwidth of the converter, from DC to 10 MHz . Therefore, the minimal jitter specification is determined at the highest input frequency. From the calculation, the aperture jitter of the input clock must be no greater than 1 ps to achieve optimal SNR performance.

## POWER DISSIPATION AND STANDBY MODE

The AD9262 power consumption can be further reduced by configuring the chip in channel power-down, standby, or sleep mode. The low power modes turn off internal blocks of the chip, including the reference. As a result, the wake-up time is dependent on the amount of circuitry that is turned off. Fewer internal circuits that are powered down result in proportionally shorter wake-up time. The low power modes are shown in Table 12. In the standby mode, all clock related activity and the output channels are disabled. Only the references and CMOS outputs remain powered up to ensure a short recovery and link integrity. During sleep mode, all internal circuits are powered down, putting the device into its lowest power mode, and the CMOS outputs are disabled.
Each ADC channel can be independently powered down or both channels can be set simultaneously by writing to the channel index, Register 0x05[1:0].

Table 12. Low Power Modes

| Mode | $\mathbf{0 x 0 8}[1: 0]$ | Analog Circuitry | Clock | Ref |
| :--- | :--- | :--- | :--- | :--- |
| Normal | $0 \times 0$ | On | On | On |
| Power-Down | $0 \times 1$ | Off | On | On |
| Standby | $0 \times 2$ | Off | Off | On |
| Sleep | $0 \times 3$ | Off | Off | Off |

## DIGITAL ENGINE

## Bandwidth Selection

The digital engine (see Figure 54) selects the decimation signal bandwidth by cascading third-order sinc ( $\operatorname{sinc}^{3}$ ) decimate-by-2 filters. For a 10 MHz signal band, no filters are cascaded; for a 5 MHz signal band, a single filter is used; and for a 2.5 MHz signal band, the 5 MHz filter is cascaded with a second filter. Depending on the signal bandwidth, this drops the data rate into the fixed decimation filter. As a result, lower signal bandwidth options result in lower power. Bandwidth selection is determined by setting Serial Register 0x0F[6:5]. Table 13 summarizes the available bandwidth options.

Table 13. Output Bandwidth Options

| BW[1:0] | AD9262BCPZ | AD9262BCPZ-5 | AD9262BCPZ-10 |
| :--- | :--- | :--- | :--- |
| $0 \times 0$ | 2.5 MHz | 5 MHz | 10 MHz |
| $0 \times 1$ | 2.5 MHz | 5 MHz | 5 MHz |
| $0 \times 2$ | 2.5 MHz | 2.5 MHz | 2.5 MHz |
| $0 \times 3$ | 2.5 MHz | 2.5 MHz | 2.5 MHz |

## Decimation Filters

The fixed decimation filters reduce the sample rate from 640 MSPS to 40 MSPS. A fixed frequency low-pass filter is used to define the signal band. This filter incorporates magnitude equalization for the droop of the preceding sinc decimation filters and the sinc filters of the sample rate converter. Table 14 and Table 15 detail the coefficients for the DEC4 and LPF/EQZ filters. Sinc filter implementation for all sinc filters is standard.

Table 14. DEC4 Filter Coefficients

## AD9262

## Sample Rate Converter

The sample rate converter (SRC) allows the flexibility of a user-defined output sample rate, enabling a more efficient and direct interface to the digital receiver blocks.
The sample rate converter performs an interpolation and resampling procedure to provide an output data rate of 20 MSPS to 168 MSPS. Table 16 and Table 17 detail the coefficients for the INT1 and INT2 filters. The sinc filters are a standard implementation.
The relationship between the output sample rate and the $\Sigma-\Delta$ modulator clock rate is expressed as follows:

$$
f_{\text {OUT }}=f_{\text {MOD }} \div K_{\text {OUT }}
$$

Table 18 shows the available Kout conversion factors.
Table 16. INT1 Filter Coefficients

| Coefficient <br> Number | Coefficient | Coefficient <br> Number | Coefficient |
| :--- | :--- | :--- | :--- |
| C0, C26 | 15 | C7, C19 | 0 |

If the main clocking source of the AD9262 is provided by the PLL, it is important, once the PLL has been programmed and locked, to initiate an SRC reset before programming the desired Kout factor. This is done by first writing $0 \times 101[5: 0]=0$ and then rewriting to the same register with the appropriate Kout value. In addition, if the AD9262 loses its clock source and then later regains it, an SRC reset should be initiated.

Table 18. SRC Conversion Factors

| $\mathbf{0 x 1 0 1 [ 5 : 0 ] ~}$ | Kout | $\mathbf{0 x 1 0 1 [ 5 : 0 ]}$ | Kout | $\mathbf{0 x 1 0 1 [ 5 : 0 ]}$ | Kout |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | SRC reset | 22 | 11 | 44 | 22 |

## Cascaded Filter Responses

The cascaded filter responses for the three signal bandwidth settings are for a 160 MSPS output data rate, as shown in Figure 55, Figure 56, and Figure 57.

Figure 55.10 MHz Signal Bandwidth, 160 MSPS

Figure 56. 5 MHz Signal Bandwidth, 160 MSPS

Figure 57. 2.5 MHz Signal Bandwidth, 160 MSPS

## DC AND QUADRATURE ERROR CORRECTION (QEC)

In direct conversion or other quadrature systems, mismatches between the real (I) and imaginary (Q) signal paths cause frequencies in the positive spectrum to image into the negative spectrum and vice versa. From an RF point of view, this is equivalent to information above the LO frequency interfering with information below the LO frequency, and vice versa. These mismatches may occur from gain and/or phase mismatches in the analog quadrature demodulator or in any components in the ADC signal chain itself. In a single-carrier zero-IF system where the carrier has been placed symmetrically around dc, this causes self-distortion of the carrier as the two sidebands fold onto one another and degrade the EVM of the signal.
In a multicarrier communication system, this can be even more problematic because carriers of widely different power levels can interfere with one another. For example, a large carrier centered at +fl can have an image appear at -fl that can be larger than the desired carrier at this frequency.
The integrated quadrature error correction (QEC) algorithm of the AD9262 attempts to measure and correct the amplitude and phase imbalances of the I and Q signal paths to achieve higher levels of image suppression than is achievable by analog means alone. These errors can be corrected in an adapted manner where the I and Q gain and quadrature phase mismatches are constantly estimated and corrected. This allows changes in the mismatches due to slow supply and temperature changes to be constantly tracked.

The quadrature errors are corrected in a frequency independent manner on the AD9262; therefore, systems with significant mismatch in the baseband chain may have reduced image suppression. The AD9262 QEC still corrects the systematic imbalances.

The convergence time of the QEC algorithm is dependent on the statistics of the input signal. For large signals and large imbalance errors, this convergence time is typically less than two million samples of the AD9262 output data rate.

## LO Leakage (DC) Correction

In a direct conversion receiver subsystem, LO to RF leakage of the quadrature modulator shows up as dc offsets at baseband. These offsets are added to dc offsets in the baseband signal paths, and both contribute to a carrier at dc. In a zero-IF receiver, this dc energy can cause problems because it appears in band of a desired channel. As part of the AD9262 QEC function, the dc offset is suppressed by applying a low frequency notch filter to form a null around dc. The 3 dB bandwidth of this notch filter vs. the AD9262 output data rates is shown in Figure 58.

## AD9262

Figure 58. DC Correction Low Frequency Notch Filter 3 dB Bandwidth vs. Output Data Rate

In applications where constant tracking of the dc offsets and quadrature errors are not needed, the algorithms can be independently frozen to save power. When frozen, the image and LO leakage (dc) correction are still performed, but changes are no longer tracked. Register 0x112[5:3] disables the respective correction when frozen.
The quadrature gain, quadrature phase, and dc correction algorithms can also be disabled independently for system debugging or to save power by setting Register 0x112[2:0].
The default configuration on the AD9262 has the QEC and dc correction blocks disabled, and Register 0x101[6] must be pulled high to enable the correction blocks. After the QEC is enabled and a correction value has been calculated, the value remains active as long as any one of the QEC functions (DC, gain, or phase correction) is used.

## QEC and DC Correction Range

Table 19 gives the minimum and maximum correction ranges of the algorithms on the AD9262 If the mismatches are greater than these ranges, an imperfect correction results.

Table 19. QEC and DC Correction Range

| Parameter | Min | Max |
| :--- | :--- | :--- |
| Gain | -1.1 dB | +1.0 dB |
| Phase | -1.79 degrees | +1.79 degrees |
| DC | $-6 \%$ | $+6 \%$ |

## DIGITAL OUTPUTS

## Digital Output Format

The AD9262 offers a variety of digital output formats for ease of system integration. The digital output on each channel consists of 16 data bits and an output clock signal (DCO) for data latching. The data bits can be configured for offset binary, twos complement, or Gray code by writing to Register 0x14[1:0]. In addition, the voltage swing of the digital outputs can be configured to 3.3 V TTL levels or a reduced voltage swing of 1.8 V by accessing Register 0x14[7]. When 3.3 V voltage levels are desirable, the DRVDD power supply must be set to 3.3 V .

## Interleaved Outputs

The AD9262 has the added feature of interleaving Channel A and Channel B data onto one 16 -bit bus. This feature is available for integer values of Kout greater than 8 and does not apply to half values of Kout. The interleave function can be accessed by writing to Register 0x14[5]. The data from both Channel A and Channel B are interleaved and presented on the Channel A bus, whereas the Channel B bus is internally grounded. Channel $A$ is sampled on the falling edge of DCO and Channel B on the rising edge. The output of Channel A and Channel B can be interchanged by inverting the DCO clock, Register 0x16[7]. In this case, Channel B is sampled on the falling edge and Channel A on the rising edge.

Figure 59. Interleaved Output Mode

## Overrange (OR) Condition

The ORA and ORB (ORx) pins serve as indicators for an overrange condition. The ORx pins are triggered by in-band signals that exceed the full-scale range of the ADC. In addition, the AD9262 possesses out-of-band gain above 10 MHz . Therefore, a large out-of-band signal may trip an overrange condition.
The ORx pins are synchronous outputs that are updated at the output data rate. Ideally, ORx should be latched on the falling edge of DCO to ensure proper setup-and-hold time. However, because an overrange condition typically extends well beyond one clock cycle (that is, it does not toggle at the DCO rate) data can usually be successfully detected on the rising edge of DCO or monitored asynchronously.
The AD9262 has two trip points that can trigger an overrange condition: analog and digital. The analog trip point is located in the modulator , and the second trip point is in the digital engine. In normal operation, it is possible for the analog trip point to toggle the ORx pin for a number of clock cycles as the analog input approaches full scale. Because the ORx pin is a pulse-width modulated (PWM) signal, as the analog input increases in amplitude, the duration of overrange pin toggling increases. Eventually, when the ORx pin is high for an extended period of time, the ADC is overloaded, whereby there is little correspondence between analog input and digital output.
The second trip point is in the digital block. If the input signal is large enough to cause the data bits to clip to its maximum fullscale level, an overrange condition occurs. The overrange trip point can be adjusted by specifying a threshold level.

Table 20 shows the corresponding threshold level in dBFS vs. register setting. If the input signal crosses this level, the ORx pin is set. In the case where $0 \times 111[5: 0]$ is set to all 0 s, the threshold level is set to the maximum code of $32,767_{10}$. This feature provides a means of reporting the instantaneous amplitude as it crosses a user-provided threshold. This gives the user a sense of the signal level without needing to perform a full power measurement.

The user has the ability to select how the overrange conditions are reported, and this is controlled through Register 0x111 via AUTORST, OR_IND, and ORTHRESH (see Table 21). By enabling the AUTORST bit, Register 0x111[7], if an overrange occurs, the ADC automatically resets itself. The ORx pins remain high until the automatic reset has completed. If an analog trip
occurs, the modulator resets itself after 16 consecutive clock cycles of overrange.
If the AD9262 is used in a system that incorporates automatic gain control (AGC), the ORx signal can be used to indicate that the signal amplitude should be reduced. This may be particularly effective for use in maximizing the signal dynamic range if the signal includes high occurrence components that occasionally exceed full scale by a small amount.

## TIMING

The AD9262 provides a data clock out (DCO) pin to assist in capturing the data in an external register. The data outputs are valid on the rising edge of DCO, unless changed by setting Serial Register 0x16[7] (see the Serial Port Interface (SPI) section). See Figure 2 for a graphical timing description.

Table 20. OR Threshold Levels

| 0x111[5:0] | Threshold (dBFS) | 0x111[5:0] | Threshold (dBFS) | 0x111[5:0] | Threshold (dBFS) |

## AD9262

## SERIAL PORT INTERFACE (SPI)

The AD9262 serial port interface (SPI) allows the user to configure the converter for specific functions or operations through a structured register space provided inside the ADC. This provides the user added flexibility and customization depending on the application. Addresses are accessed via the serial port and can be written to or read from via the port. Memory is organized into bytes that are further divided into fields, as documented in the Memory Map section. For detailed operational information, see the AN-877 Application Note, Interfacing to High Speed ADCs via SPI.

## CONFIGURATION USING THE SPI

As summarized in Table 22, three pins define the SPI of this ADC. The SCLK pin synchronizes the read and write data presented to the ADC. The SDIO pin allows data to be sent and read from the internal ADC memory map registers. The CSB pin is an active low control that enables or disables the read and write cycles.

Table 22. Serial Port Interface Pins

| Pin Name | Description |
| :--- | :--- |
| SCLK | SCLK (serial clock) is the serial shift clock. SCLK <br> synchronizes serial interface reads and writes. |
| SDIO | SDIO (serial data input/output) is an input and <br> output depending on the instruction being sent <br> and the relative position in the timing frame. <br> CSB (chip select bar) is an active low control that <br> gates the read and write cycles. |

The falling edge of CSB in conjunction with the rising edge of SCLK determines the start of the framing. Figure 60 and Table 23 provide an example of the serial timing and its definitions.
Other modes involving CSB are available. CSB can be held low indefinitely to permanently enable the device (this is called streaming). CSB can stall high between bytes to allow for additional external timing. When CSB is tied high, SPI functions are placed in a high impedance mode.

During an instruction phase, a 16-bit instruction is transmitted. Data follows the instruction phase, and the length is determined by the W0 bit and the W1 bit. All data is composed of 8 -bit words. The first bit of each individual byte of serial data indicates whether a read or write command is issued. This allows the serial data input/output (SDIO) pin to change direction from an input to an output.
In addition to word length, the instruction phase determines if the serial frame is a read or write operation, allowing the serial port to be used to both program the chip and to read the contents of the on-chip memory. If the instruction is a readback operation, performing a readback causes the serial data input/output (SDIO) pin to change direction from an input to an output at the appropriate point in the serial frame.
Data can be sent in MSB-first or in LSB-first mode. MSB first is the default setting on power-up and can be changed via the configuration register. For more information, see the AN-877 Application Note, Interfacing to High Speed ADCs via SPI.

Table 23. SPI Timing Diagram Specifications

| Parameter | Description |
| :--- | :--- |
| $\mathrm{t}_{\text {SDS }}$ | Setup time between data and rising edge of SCLK |
| $\mathrm{t}_{\text {SDH }}$ | Hold time between data and rising edge of SCLK |
| $\mathrm{t}_{\text {SCLK }}$ | Period of the clock |
| $\mathrm{t}_{\text {sS }}$ | Setup time between CSB and SCLK |
| $\mathrm{t}_{\text {SH }}$ | Hold time between CSB and SCLK |
| $\mathrm{t}_{\text {SHIGH }}$ | Minimum period that SCLK should be in a logic <br> high state |
| $\mathrm{t}_{\text {sLow }}$ | Minimum period that SCLK should be in a logic <br> low state |

Figure 60. Serial Port Interface Timing Diagram

## HARDWARE INTERFACE

The pins described in Table 22 comprise the physical interface between the programming device of the user and the serial port of the AD9262. The SCLK and CSB pins function as inputs when using the SPI interface. The SDIO pin is bidirectional, functioning as an input during write phases and as an output during readback.

The SPI interface is flexible enough to be controlled by either PROM or PIC microcontrollers. This provides the user with the ability to use an alternate method to program the ADC. One such method is described in detail in the AN-812 Application Note, MicroController-Based Serial Port Interface (SPI) Boot Circuit.

## APPLICATIONS INFORMATION

## FILTERING REQUIREMENT

The need for antialias protection often requires one or two octaves for a transition band, which reduces the usable bandwidth of a Nyquist converter to between $25 \%$ and $50 \%$ of the available bandwidth. A CT $\Sigma-\Delta$ converter maximizes the available signal bandwidth by forgoing the need for an anti-aliasing filter because the architecture possesses inherent anti-aliasing. Although a high order, sharp cutoff antialiasing filter may not be necessary because of the unique characteristics of the architecture, a low order filter may still be required to precede the ADC for out-of-band signal handling.
Depending on the application and the system architecture, this low order filter may or may not be necessary. The signal transfer function (STF) of a continuous time feedforward ADC usually contains out-of-band peaks. Because these STF peaks are typically one or two octaves above the pass-band edge, they are not problematic in applications where the bulk of the signal energy is in or near the pass band. However, in applications with large far-out interferers, it is necessary to either add a filter to attenuate these problematic signals or to allocate some of the ADC dynamic range to accommodate them.
Figure 61 shows the normalized STF of the AD9262 CT $\Sigma-\Delta$ converter. The figure shows out-of-band peaking beyond the band edge of the ADC. Within the 10 MHz band of interest, the STF is maximally flat with less than 0.1 dB of gain. Maximum peaking occurs at 60 MHz with 10 dB of gain. To put this into perspective, for a fixed input power, a 5 MHz in-band signal appears at -5 dBFS , a 25 MHz tone appears at -2 dBFS and 60 MHz tone at +5 dBFS . Because the maximum input to the ADC is -2 dBFS , large out-of-band signals can quickly saturate the system. This implies that, under these conditions, the digital outputs of the ADC no longer accurately represent the input. See the Overrange (OR) Condition section for details on overrange detection and recovery.

Figure 61. STF

Figure 61 shows the gain profile of the AD9262, and this can be interpreted as the level at which the signal power should be scaled back to prevent an overload condition. This is the ultimate trip point and before this point is reached, the in-band noise (IBN) slowly degrades. As a result, it is recommended that the low-pass filter be designed to match the profile of Figure 62, which shows the maximum input signal for a 3 dB degradation of in-band noise. The input signal is attenuated to allow only 3 dB of noise degradation over frequency.

The noise performance is normalized to a -2 dBFS in-band signal. The AD9262 STF and NTF are flat within the band of interest and should result in almost no change in input level and IBN. Beyond the bandwidth of the AD9262, out-of-band peaking adds gain to the system, therefore requiring the input power to be scaled back to prevent in-band noise degradation. The input power is scaled back to a point where only 3 dB of noise degradation is allowed, therefore resulting in the response shown in Figure 62.

Figure 62. Maximum Input Level for $3 d B$ Noise Degradation
An example third-order, low-pass Chebyshev II type filter is shown in Figure 63. Table 24 summarizes the components and manufacturers used to build the circuit.

Figure 63. Third-Order, Low-Pass Chebyshev II Filter

Table 24. Chebyshev II Filter Components

| Parameter | Value | Unit | Manufacturer |
| :--- | :--- | :--- | :--- |
| C1 | 18 | pF | Murata GRM188 series, 0603 |
| L1 | 180 | nH | Coil Craft 0603 LS, 2\% |
| C2 | 390 | pF | Murata GRM188 series, 0603 |
| C3 | 150 | pF | Murata GRM188 series, 0603 |

In addition to matching the profile of Figure 62, group delay and channel matching are important filter design criteria. Low tolerance components are highly recommended for improved channel matching, which translates to minimal degradation in image rejection for quadrature systems.

## AD9262

## OUTLINE DIMENSIONS

## ORDERING GUIDE

| Model $^{1}$ | Temperature Range | Package Description | Package Option |
| :--- | :--- | :--- | :--- |
| AD9262BCPZ-10 | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 64-Lead Lead Frame Chip Scale Package [LFCSP_VQ] | CP-64-4 |
| AD9262BCPZ-5 | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 64-Lead Lead Frame Chip Scale Package [LFCSP_VQ] | CP-64-4 |
| AD9262BCPZ | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | 64-Lead Lead Frame Chip Scale Package [LFCSP_VQ] | CP-64-4 |
| AD9262EBZ |  | Evaluation Board |  |
| AD9262-5EBZ | Evaluation Board |  |  |
| AD9262-10EBZ | Evaluation Board |  |  |

${ }^{1} Z=$ RoHS Compliant Part.

[^0]:    ${ }^{1}$ Input power is referenced to full scale. Therefore, all measurements were taken with a 2 dB signal below full scale, unless otherwise noted.
    ${ }^{2}$ Measured with a low input frequency, full-scale sine wave.

[^1]:    ${ }^{1}$ See the AN-835 Application Note, Understanding High Speed ADC Testing and Evaluation, for a complete set of definitions.
    ${ }^{2}$ Data guaranteed over the full temperature range for the AD9262BCPZ only.
    ${ }^{3}$ Data guaranteed over the full temperature range for the AD9262BCPZ-5 only.
    ${ }^{4}$ Data guaranteed over the full temperature range for the AD9262BCPZ-10 only.
    ${ }^{5}$ Noise figure with respect to $50 \Omega$. AD9262 internal impedance is $1000 \Omega$ differential. See the AN-835 Application Note for a definition.
    ${ }^{6}$ Crosstalk measured with an input signal on both channels at different frequencies and the leakage of one on to the other.

[^2]:    ${ }^{1}$ See the AN-835 Application Note, Understanding High Speed ADC Testing and Evaluation, for a complete set of definitions.

[^3]:    ${ }^{1}$ See the AN-835 Application Note, Understanding High Speed ADC Testing and Evaluation, for a complete set of definitions.
